c. PM2.5 number of stations

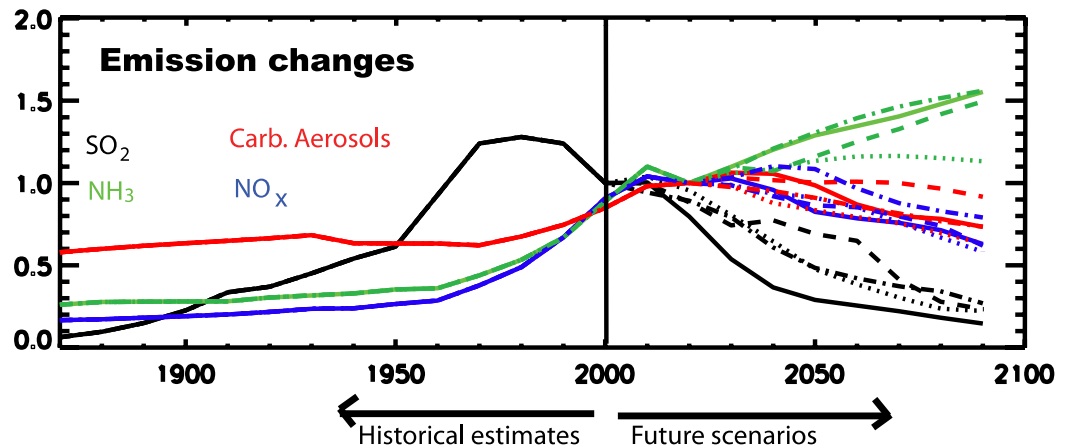

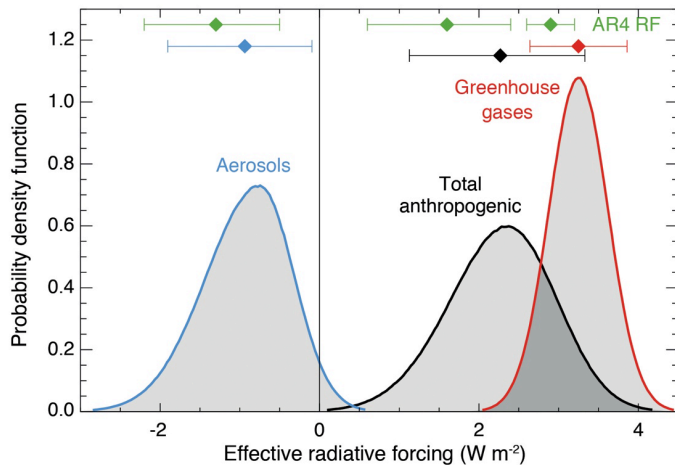

~14,000 stations
>20 million obs
includes data outside of US and Europe

Aerosols important for understanding climate

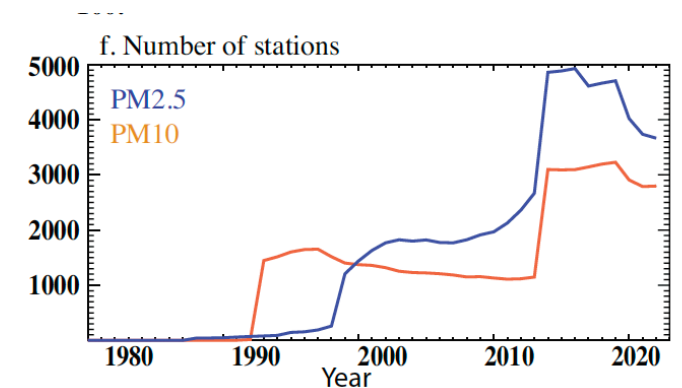

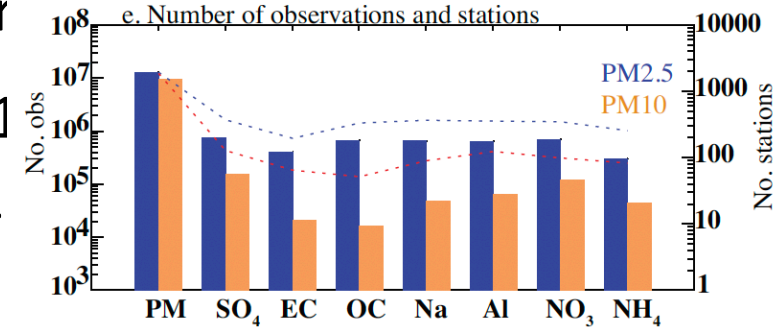

- Aerosols large source of uncertainty in current radiative forcing and PI/PD changes
- Different aerosol sources have different trends going into the future
- Different aerosols have different impacts (warming versus cooling, cloud interactions, biogeochemistry)

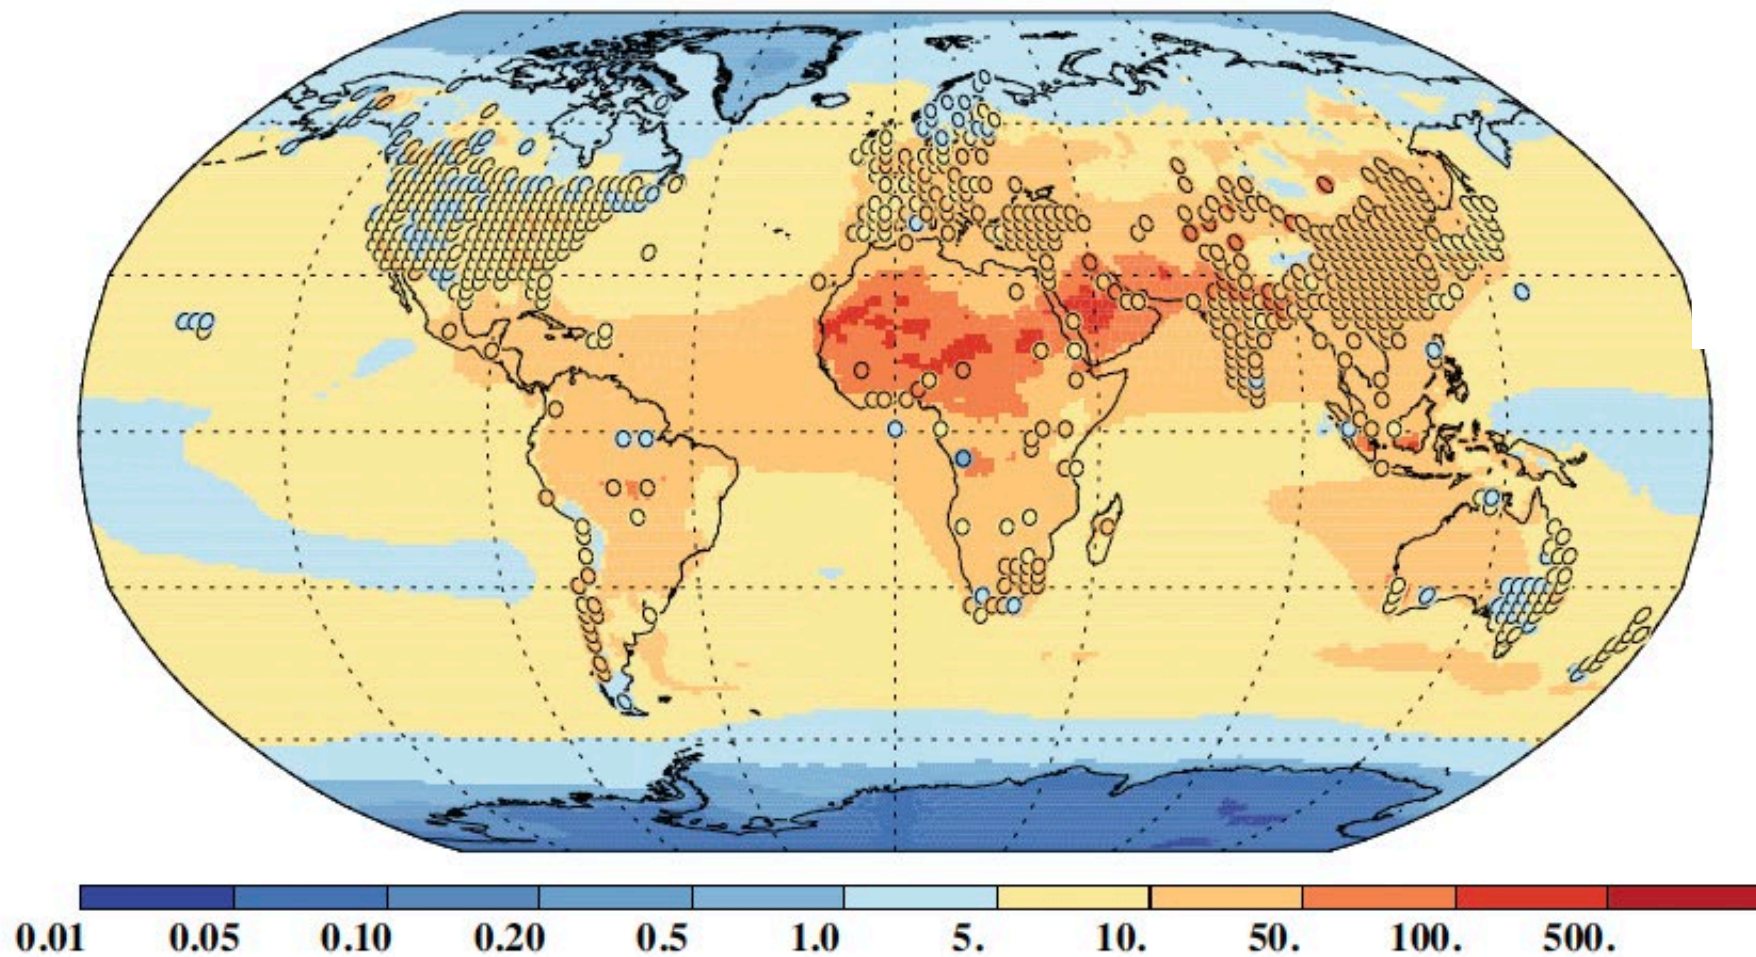

Methodology

- Compile total PM, SO₄, EC/BC, OM/OC, Na, Al, NO₃ and NH₄ for PM_{2.5} and PM₁₀ at the daily to weekly level globally (much more data available than in previous datasets (Szopa et al., 2021))
- This is the first paper presenting annual means across 1986-2021 time period. More papers will follow with temporal resolution
- Compare to CESM model (default)+ added NO₃/NH₄ from Vira et al., 2021
- Add in other sources:
 - Agricultural dust (tuned to Ginoux et al., 2012 satellite estimate)
 - Road dust, industrial emissions, coarse OC and BC (from Klimont et al. 2017)
 - Add in primary biogenic emissions (Mahowald et al., 2005; Burrows et al., 2009; Heald and Spracklen 2009)
- Average to 2x2 grid for display (where there is data there is often too much to display)
- Convert modeled composition to observed composition when needed (e.g. dust to Al or sea salts to Na).

PM2.5

a. PM2.5 (ug/m³)

Gridded comparison

c. PM2.5 (ug/m³)

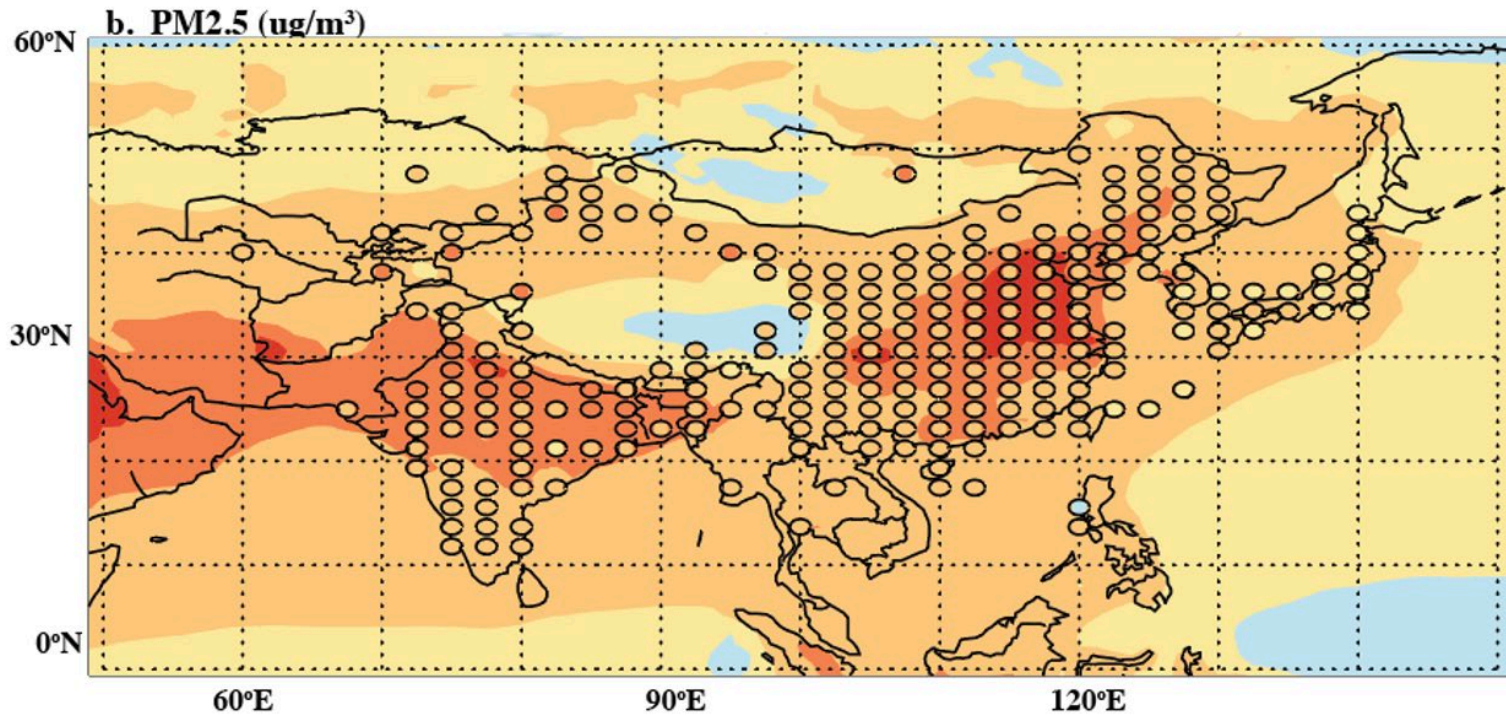

◇ Australia × Europe
+ Asia △ Africa
ungridded comparison

d. PM2.5 (ug/m³)

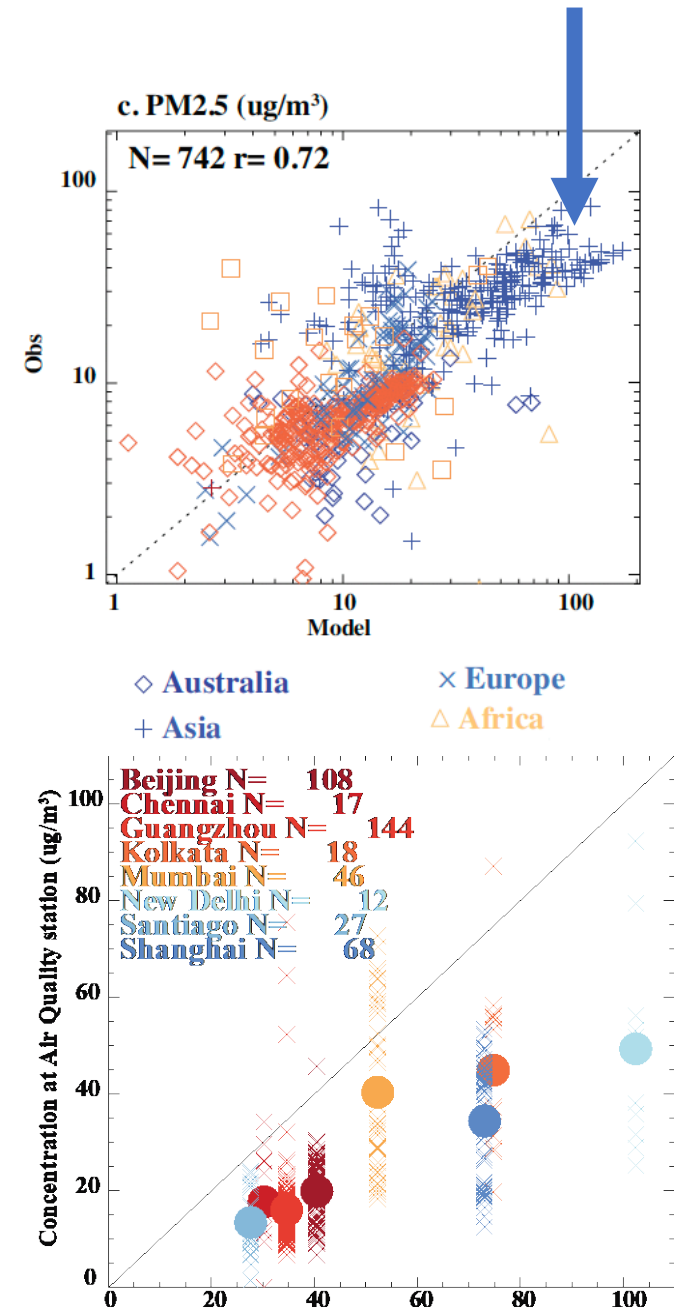

□ South America + High Latitudes
◇ North America

Model too high over Asia?

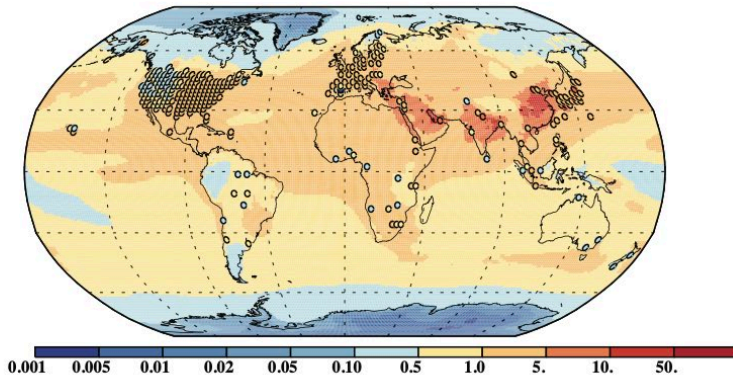

Included a lot of new data from China and India: there seems to be a systematic bias between Chinese and Indian air quality data versus US embassy data: unclear why.

Compare by constituent as well.

a. SO_4 PM_{2.5} $\mu\text{g}/\text{m}^3$

b. SO_4 PM_{2.5} $\mu\text{g}/\text{m}^3$

c. BC PM_{2.5} $\mu\text{g}/\text{m}^3$

d. BC PM_{2.5} $\mu\text{g}/\text{m}^3$

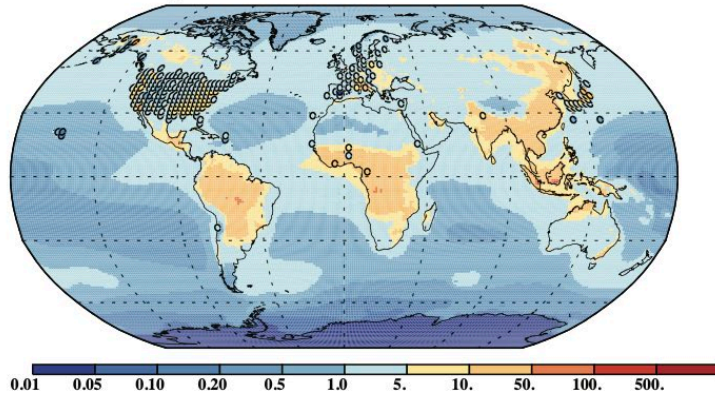

Model SO_4 too high
BC/EC about right

Much less data than PM

Liu et al., 2011, 2016

PM2.5 constituents

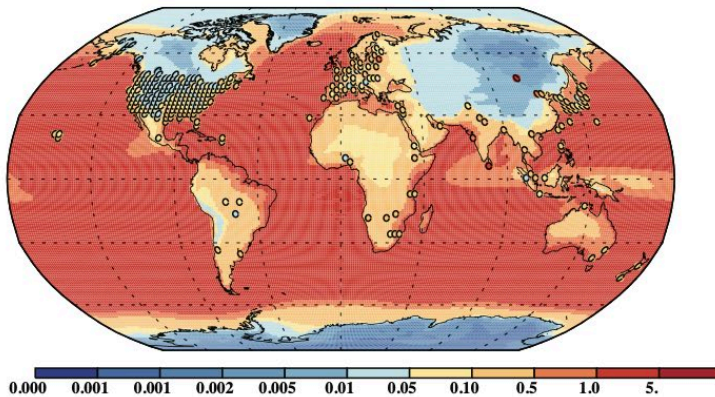

e. OM PM2.5 ug/m³

f. OM PM2.5 ug/m³

g. Na PM2.5 ug/m³

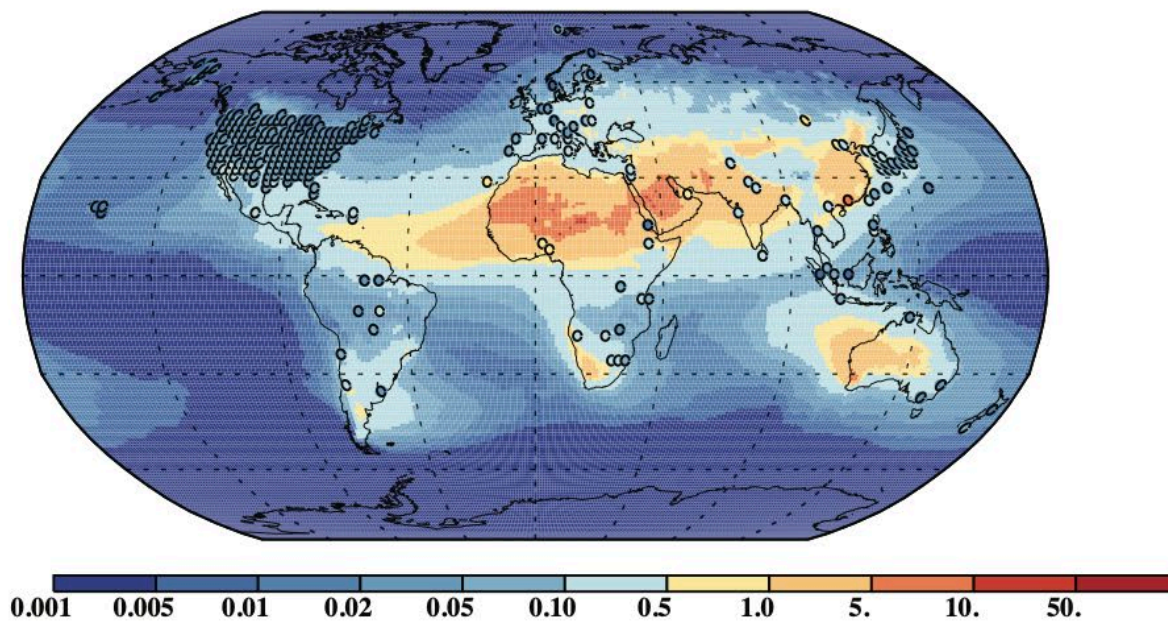

h. Na PM2.5 ug/m³

- OM/OC: a little high: much less data
- Na: model too flat compared to obs. (need industrial source of Na?)

Al/dust

i. Al PM_{2.5} ug/m³

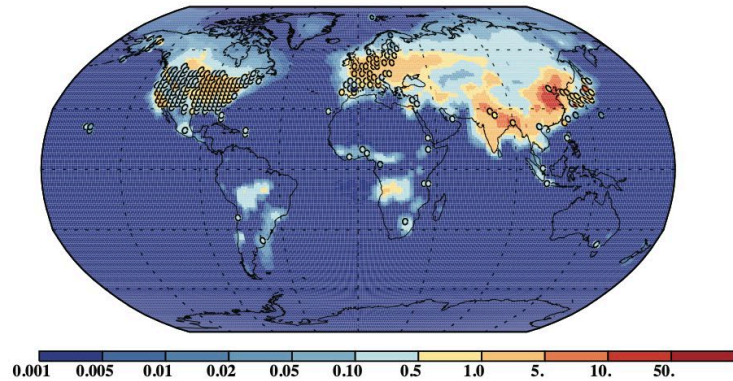

j. Al PM_{2.5} ug/m³

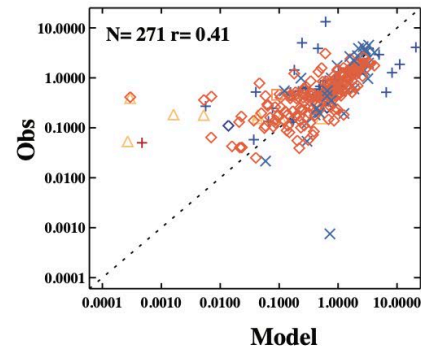

PM2.5 Nitrogen aerosols

k. NO_3 PM2.5 $\mu\text{g}/\text{m}^3$

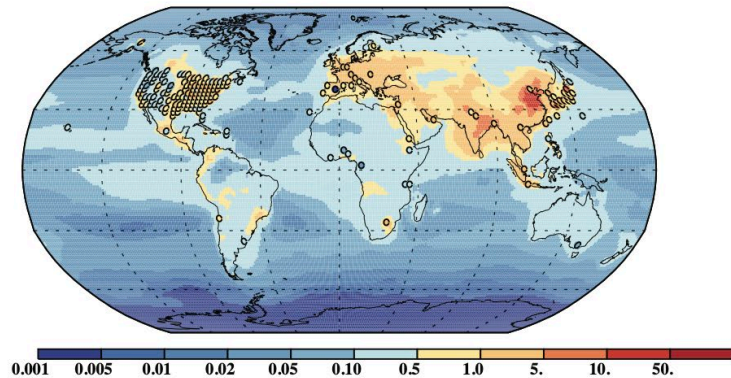

l. NO_3 PM2.5 $\mu\text{g}/\text{m}^3$

Needed to half NO_3 (Vira et al., 2021)
(likely because no thermodynamic model)

m. NH_4 PM2.5 $\mu\text{g}/\text{m}^3$

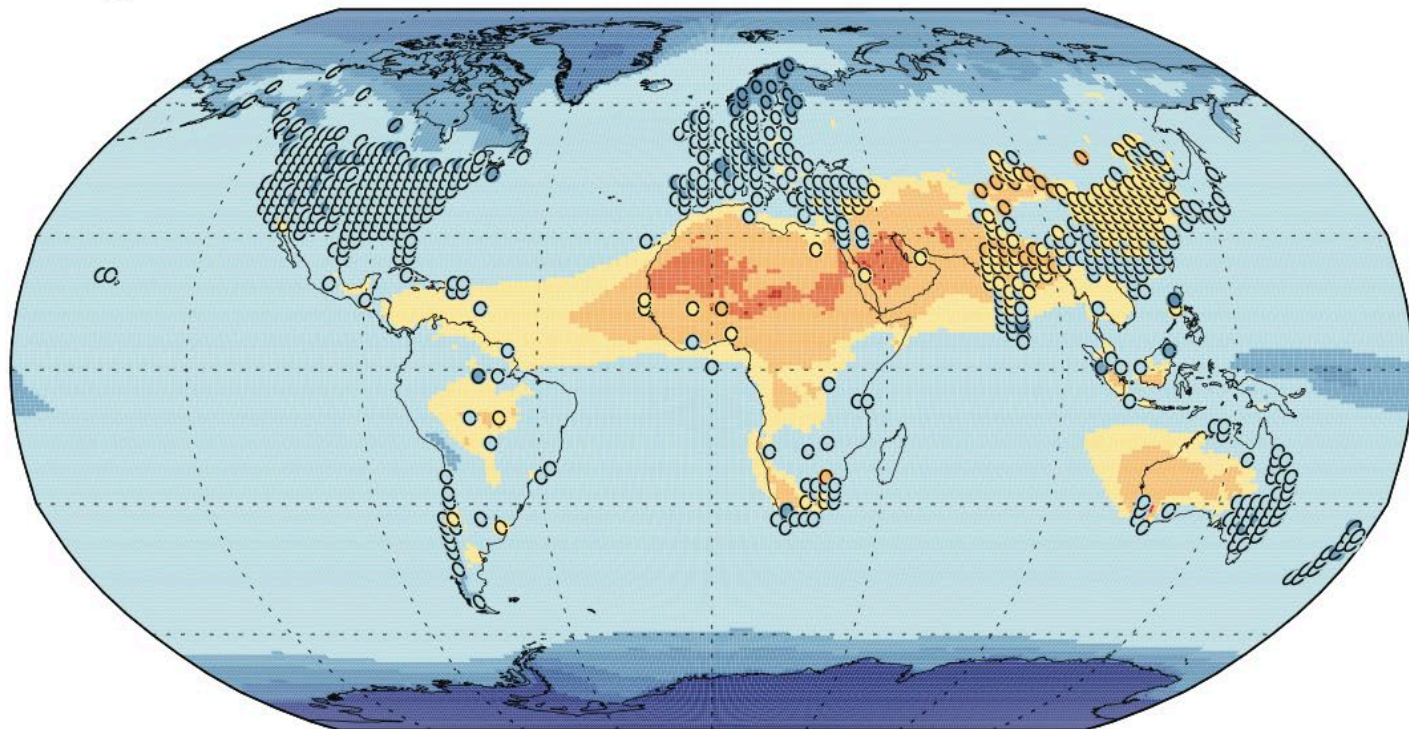

n. NH_4 PM2.5 $\mu\text{g}/\text{m}^3$

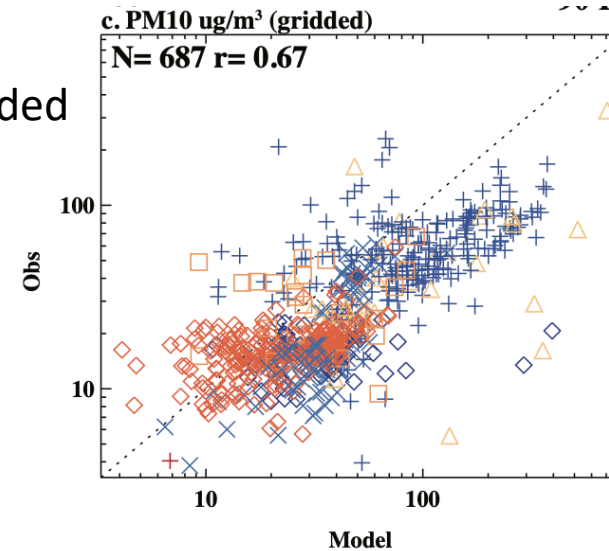

PM10

a. PM10 ug/m³

gridded

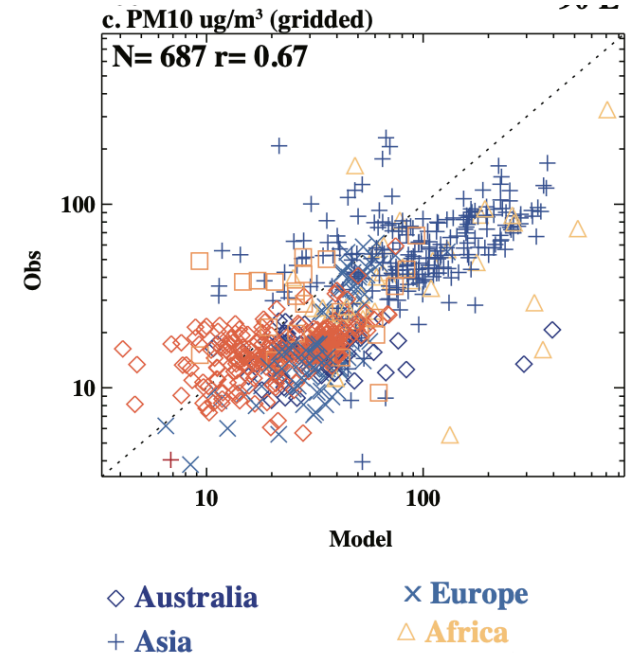

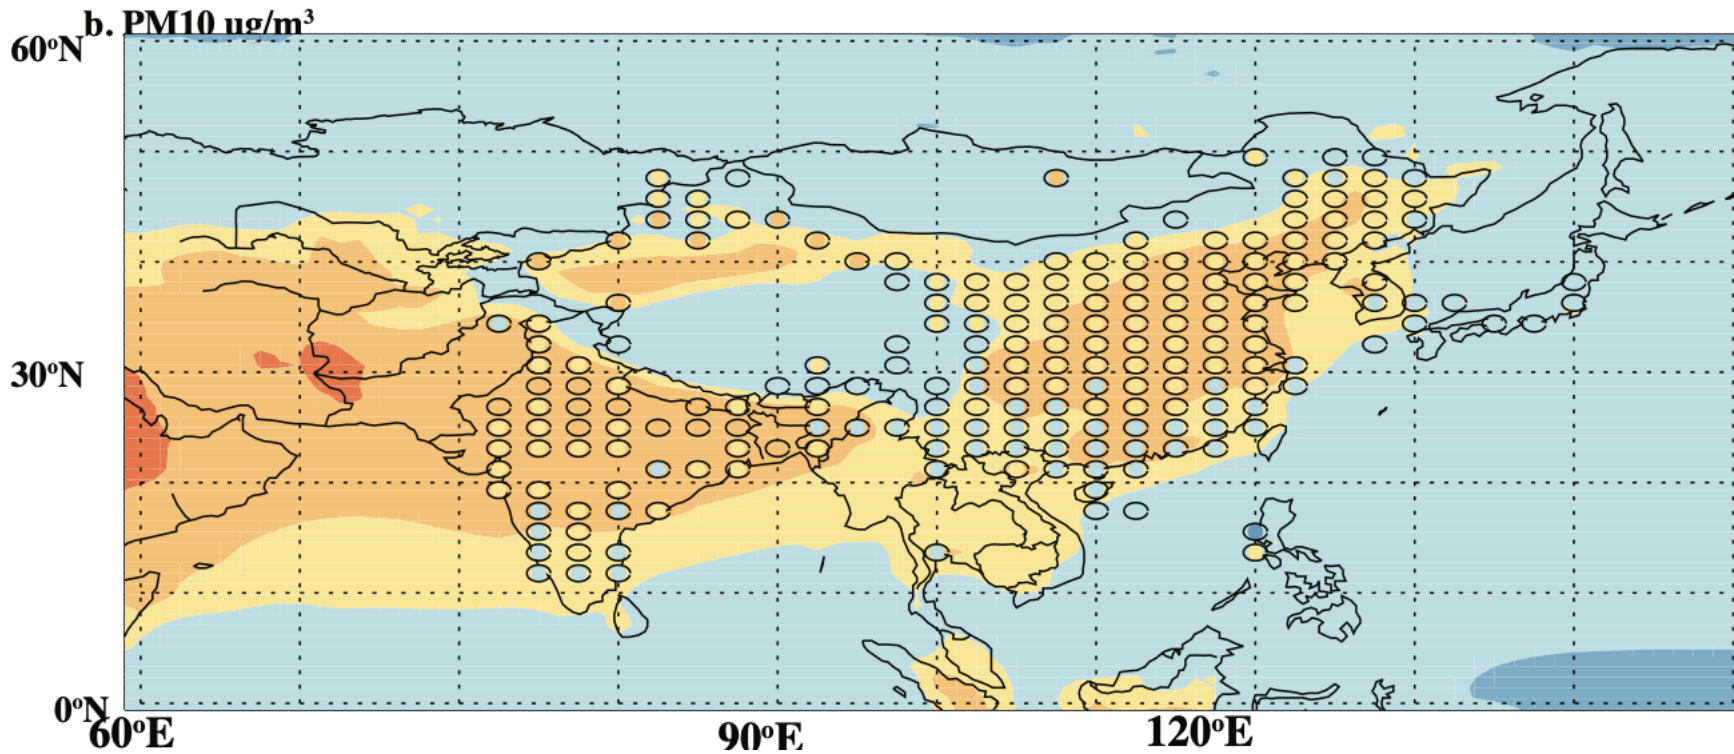

- ◇ Australia
- × Europe
- + Asia
- △ Africa

ungridded

- South America
- + High Latitudes
- ◇ North America

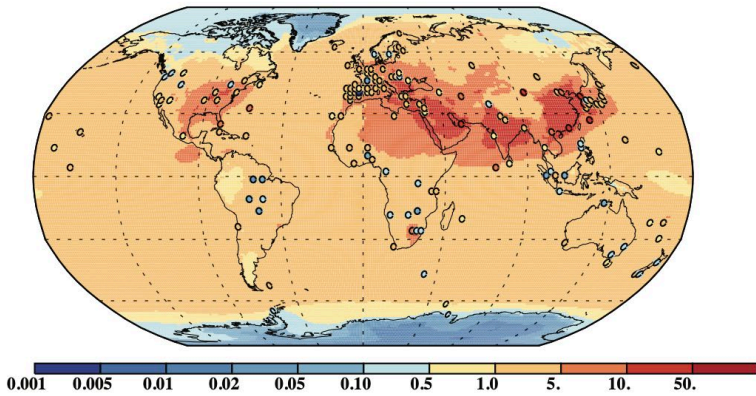

Similar bias over asia?

Or new data not representative?

PM10 sulfate and BC/EC

a. SO₄ PM10 ug/m³

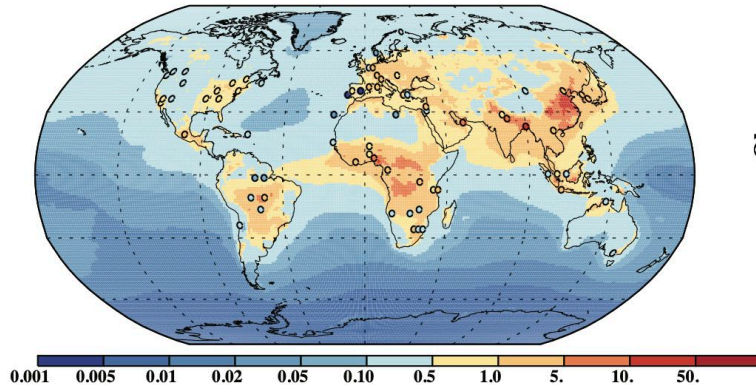

b. SO₄ PM2.5 ug/m³

Model over estimates sulfate in coarse mode

c. BC PM10 ug/m³

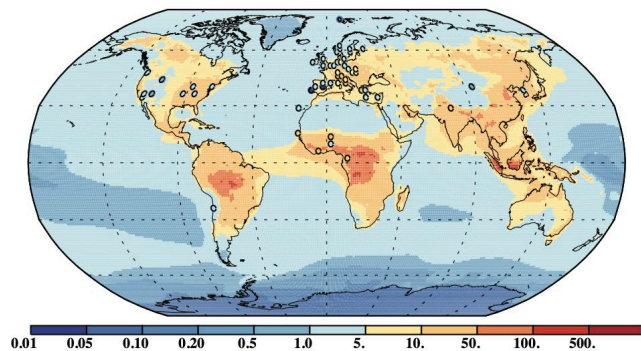

c. BC PM2.5 ug/m³

Added BC into coarse mode: maybe too much?

PM10 OC/OM and seasalts/Na

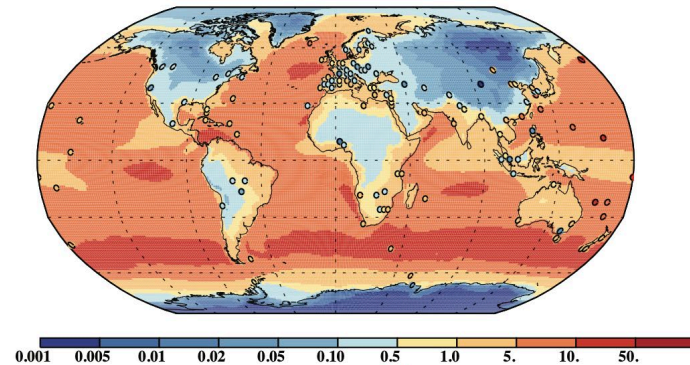

e. OM PM10 ug/m³

f. OM PM10 ug/m³

g. Na PM10 ug/m³

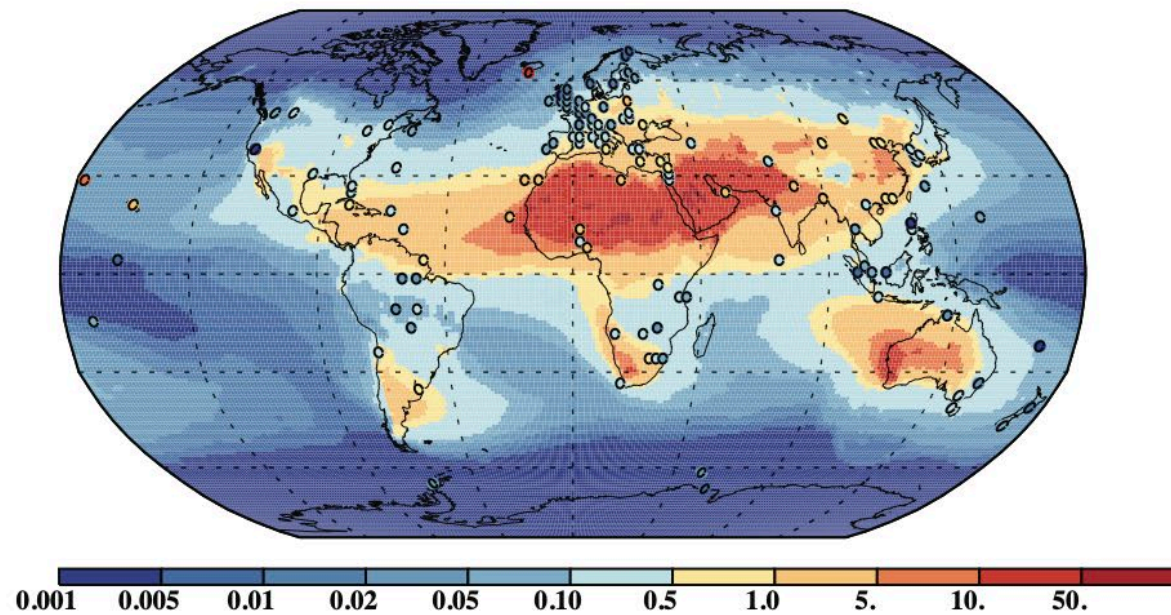

h. Na PM10 ug/m³

- ◇ Australia
- × Europe
- South America
- + High Latitudes
- + Asia
- △ Africa
- ◇ North America

Dust/Al

i. Al PM10 $\mu\text{g}/\text{m}^3$

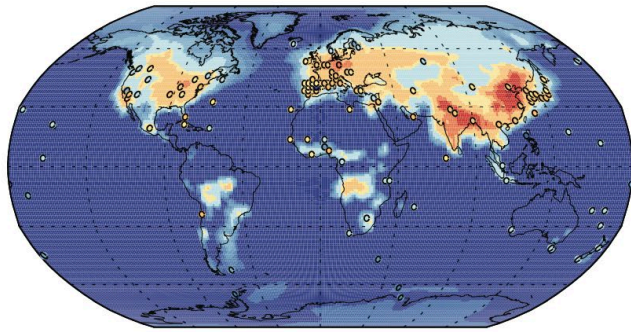

j. Al PM10 $\mu\text{g}/\text{m}^3$

PM10 NO3 and NH4

k. NO₃ PM10 ug/m³

m. NH₄ PM10 ug/m³

l. NO₃ PM10 ug/m³

Model doesn't differentiate coarse versus fine, so this is all nitrogen

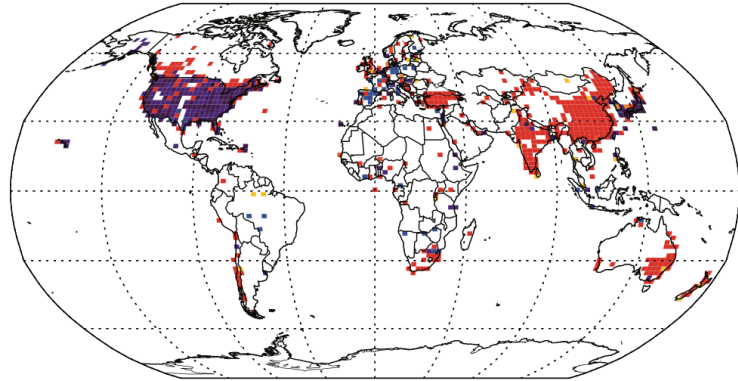

It's very hard to get N aerosols right without thermodynamic model which was not in Vira et al., 2021.

n. NH₄ PM10 ug/m³

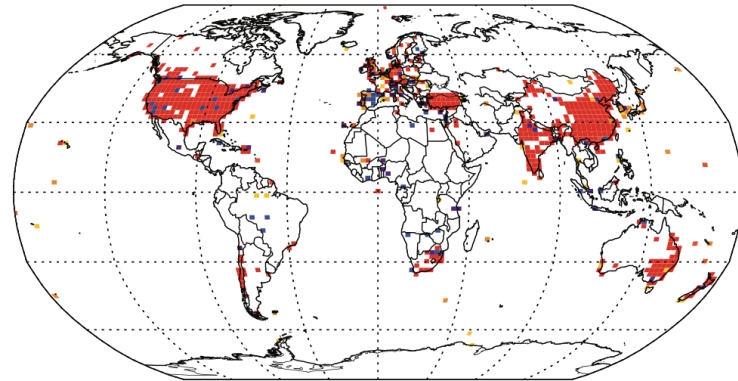

Most areas of the globe or even of land have no data

a. PM2.5 coverage (%)

b. PM10 coverage (%)

Red: only PM, blue/purple also composition

3% of land is covered by observations of aerosol.

Surface aerosol amount and important composition is not well measured.

Cannot get composition from remote sensing.

N aerosols are going up, sulfate down: don't know where they are (Adams et al., 2001; Bauer et al., 2007)

Need more in situ data.

CESM does not include many important aerosols

a. PM2.5 concentration default sources (%)

b. PM2.5 concentration new sources (%)

c. PM10 concentration default sources (%)

d. PM10 concentration new sources (%)

- Most important: N aerosols: need for climate simulations
 - 30% of aerosols
 - Have different trends (upward due to land use) than sulfate (downward due to less fossil fuels)
- Also: agricultural dust important to include
- (other additions didn't matter as much: road dust, coarse mode EC/BC, PBPs...)

Summary conclusions

- New annual compilation for use in comparing model aerosols to data
 - Much more data in non-US and non-European areas in this compilation
- Temporal variability will be next! (other ideas: glad to collaborate)
- Includes composition data as available
- **Need more in situ data to constrain current distribution of aerosols**
- **Models need to include N aerosols and agricultural dust or they are missing important aerosol trends.**
- (Aerosols even more unconstrained if we look farther back than 1980: see Mahowald et al., 2024, ACP).
