SPACE - TIME SCALES and OCEAN MODELS

PARAMETERIZATIONS:

- ACCOMPLISH PHYSICAL EFFECTS OF UNRESOLVED SUB-GRID-SCALE PROCESSES (ALL INVOLVING TURBULENCE),
- PHYSICALLY-BASED / JUSTIFIED,
- AS SIMPLE AS POSSIBLE,
- AS FEW PARAMETERS AS POSSIBLE.
 - Development,
 - Implementation,
 - Verification,
 - Impacts

PARAMETERIZATIONS IN CESM1 POP2

- Vertical mixing (momentum and tracers)
 - surface boundary layer,
 - interior
- Horizontal viscosity (momentum)
- Lateral mixing / mesoscale eddies (tracers)
- Overflows
- Submesoscale eddies (tracers)
- Diurnal cycle for short-wave heat flux
- Solar absorption
- Langmuir circulation
- Near-inertial wave mixing

VERTICAL MIXING SCHEME: K-PROFILE PARAMETERIZATION (KPP)

Large, McWilliams, and Doney (1994, Rev. Geophys.)

A first-order turbulent closure scheme

$$\partial_t X = -\partial_z \overline{w' X'}$$

where X is a generalized variable (i.e., U, θ , etc.), w is the vertical velocity component, and the primes denote turbulent fluctuations.

$$\overline{w'X'} = -K_X \ \partial_z X$$

where K_X is an eddy diffusivity or viscosity.

KPP involves three high-level steps:

- 1. Determination of boundary layer depth,
- 2. Calculation of interior diffusivities,
- 3. Evaluation of boundary layer diffusivities.

KPP BOUNDARY LAYER DEPTH

The boundary layer depth, h, is determined based on a bulk Richardson number,

$$Ri_b(d) = \frac{[B_r - B(d)] d}{|\mathbf{V}_r - \mathbf{V}(d)|^2 + V_t^2(d)}$$

where d is depth. Also

- \mathbf{V}_r : near-surface reference horizontal velocity vector
- $\mathbf{V}(d)$: boundary layer horizontal velocity profile
- B_r : near-surface reference buoyancy
- B(d): boundary layer buoyancy profile
- V_t : velocity scale of turbulent velocity shear

h is equated to the smallest value of d at which the bulk Ri equals Ri_{cr}=0.3.

INTERIOR MIXING

- Shear instability: K_X^{s}
- Internal wave breaking: K_X^{w}
- Double diffusion: K_X^{d}
- Local static instability (convection): K_X^{c}
- Tidal mixing: K_X^{\dagger}

$$K_{X}(interior) = K_{X}^{s} + K_{X}^{w} + K_{X}^{d} + K_{X}^{c} + K_{X}^{\dagger}$$

KPP BOUNDARY LAYER MIXING

 $K_{X}(l) = h \ w_{X}(l) \ G(l)$ with l = d / h, $w_{X}(l): turbulent velocity scale,$

G(1): cubic shape function.

- K_X is non-local,
- Interior mixing at the base of the boundary layer influences the turbulence throughout the boundary layer,
- There is also a non-local counter-gradient term.

HORIZONTAL VISCOSITY

Spatially uniform, isotropic, Cartesian, Δ =250km grid for illustration

$$D(U) = A \quad U_{xx} + A \quad U_{yy}$$
$$D(V) = A \quad V_{xx} + A \quad V_{yy}$$

Grid Re (Diffuse Noise) \rightarrow A > 0.5 V Δ = 100,000 m²/sResolve WBC (Munk Layers) \rightarrow A > β Δ^3 = 80,000 m²/sDiffusive CFL \rightarrow A < 0.5 Δ^2 / Δ t = 8000,000 m²/sRealism (EUC, WBC) \rightarrow A ~ physical = 1,000 m²/sSmagorinsky \rightarrow A = C $\Delta^2 \int (\partial_x U)^2 + (\partial_y V)^2 + (\partial_x V + \partial_y U)^2$

ANISOTROPIC HORIZONTAL VISCOSITY

$$\partial_{t} u + \dots = \partial_{x} (A \partial_{x} u) + \partial_{y} (B \partial_{y} u)$$
$$\partial_{t} v + \dots = \partial_{x} (B \partial_{x} v) + \partial_{y} (A \partial_{y} v)$$

Grid Re (Diffuse Noise) \rightarrow Live with the "noise"

Resolve WBC (Munk Layers) $\rightarrow A = B = \beta \Delta^3$, only near WBC

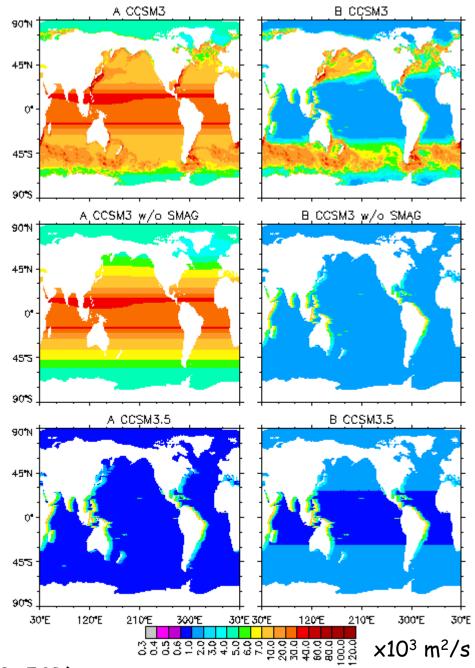

elsewhere: Realism (EUC, WBC) → A = 300 m²/s B = 300 m²/s in the tropics = 600 m²/s polewards of 30°

Subject to diffusive CFL, but NO Smagorinsky

ANISOTROPIC HORIZONTAL VISCOSITY at 100-m DEPTH

CCSM4 Ocean :

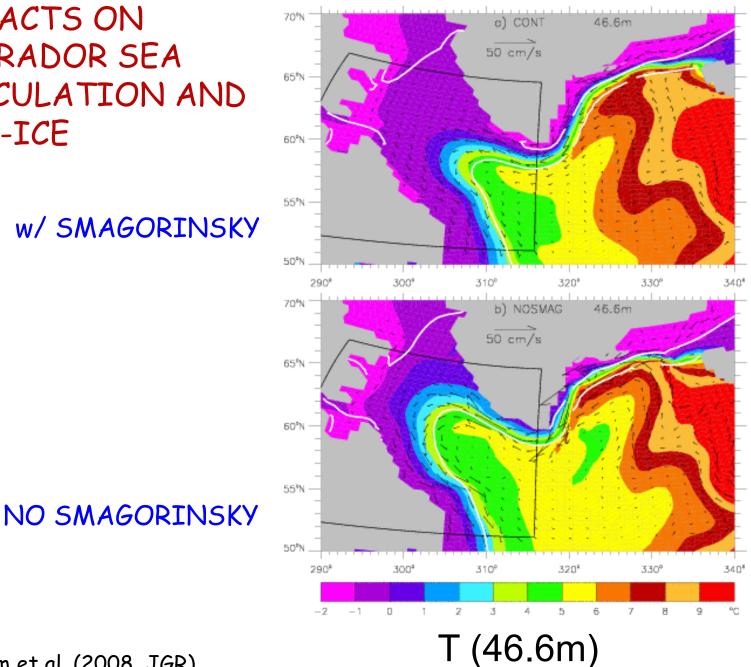

- -Minimally Numerically Viscous
- -Maximally Physically Viscous

MESOSCALE EDDY PARAMETERIZATION FOR TRACERS

Ocean Observations suggest mixing along isopycnals is $\sim 10^7$ times larger than across isopycnals. Horizontal mixing causes spurious diapycnal mixing.

An example: The Veronis (1975) effect

For steady WBC ... $W\rho_z = K\rho_{xx}$

GENT & McWILLIAMS (1990) MESOSCALE EDDY PARAMETERIZATION

Mimics effects of unresolved mesoscale eddies as a sum of

- diffusive mixing of tracers along isopycnals (Redi),
- an additional advection of tracers by an eddy-induced velocity (u*, divergence-free),

Quasi-adiabatic and valid for the ocean interior,

Flattens isopycnals, thereby reducing potential energy,

Eliminates any need for horizontal diffusion, no Veronis effect.

Gent & McWilliams (1990, JPO)

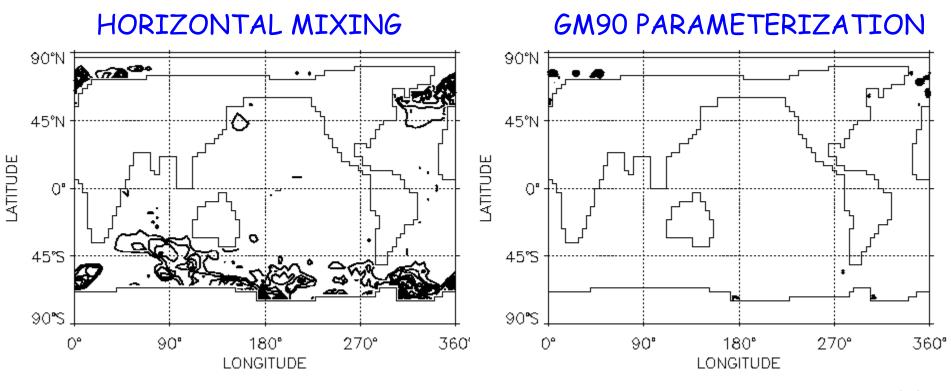

GENT & McWILLIAMS (1990) MESOSCALE EDDY PARAMETERIZATION

$$\frac{\partial T}{\partial t} + \nabla_{3D} \cdot (\mathbf{u} + \mathbf{u}^{*})T = \nabla_{3D} \cdot \mathbf{K}^{\rho} \nabla_{3D} T + F^{*}$$
$$(u^{*}, v^{*}) = -\frac{\partial}{\partial z} (A_{ITD} \mathbf{S}) \qquad w^{*} = \nabla \cdot (A_{ITD} \mathbf{S})$$

Here, T is a generic tracer, s is the 2D isopycnal slope vector, and K is the isopycnal diffusion tensor.

There are two diffusivities: A_{I} : isopycnal in K, A_{ITD} : thickness

IMPACTS ON DEEP WATER FORMATION / CONVECTION

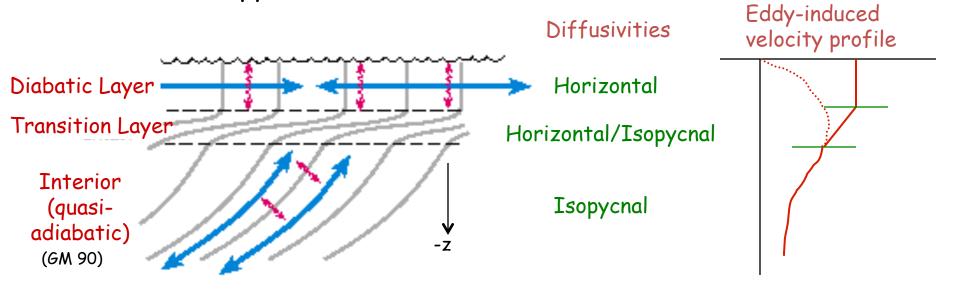

4°x3°x20L ocean model

Danabasoglu et al. (1994, Science)

NEAR-SURFACE EDDY FLUX (NSEF) SCHEME

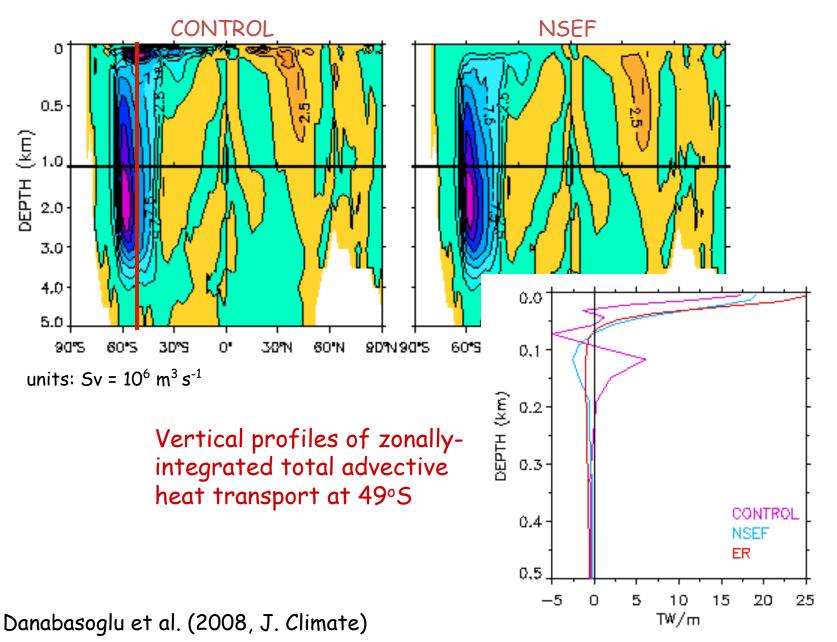

GM90 is valid only in the quasi-adiabatic ocean interior, therefore the usual practice has been to taper both A_{I} and A_{ITD} to zero as the surface is approached.

NSEF replaces the usual approach of applying near-surface taper functions for the diffusivities.

Ferrari et al. (2008, J. Climate), Danabasoglu et al. (2008, J. Climate)

EDDY-INDUCED MERIDIONAL OVERTURNING CIRCULATION

SPATIAL VARIATIONS OF THE EDDY DIFFUSIVITIES

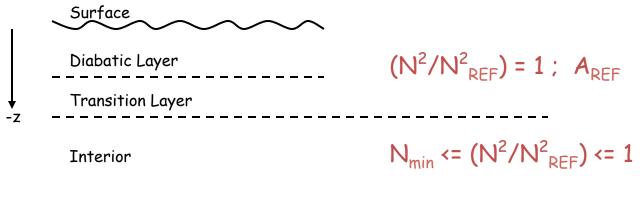

Following Ferreira et al. (2005), the diffusivities are specified as

 $A = A_{REF} (N^2 / N_{REF}^2)$

N²: Local buoyancy frequency,

N²_{REF}: Reference buoyancy frequency just below the transition layer,

 A_{REF} : Constant reference value of A within the surface diabatic region.

 N_{min} is a lower limit, $N_{min} = 0.1$.

Ferreira et al. (2005, JPO)

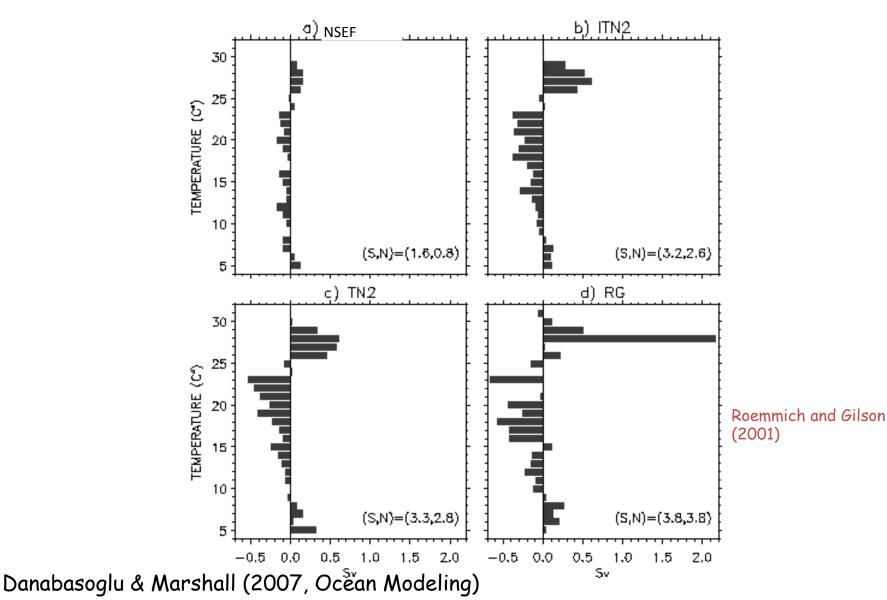

THICKNESS DIFFUSIVITY

Danabasoglu & Marshall (2007, Ocean Modelling)

Model Eddy-Induced Transport Comparisons with Roemmich and Gilson (2001) Observational Estimate

(Repeat hydrographic line in the North Pacific at an average latitude of 22°N)

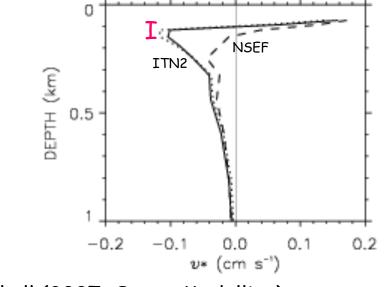

The eddy-induced meridional velocity is given by

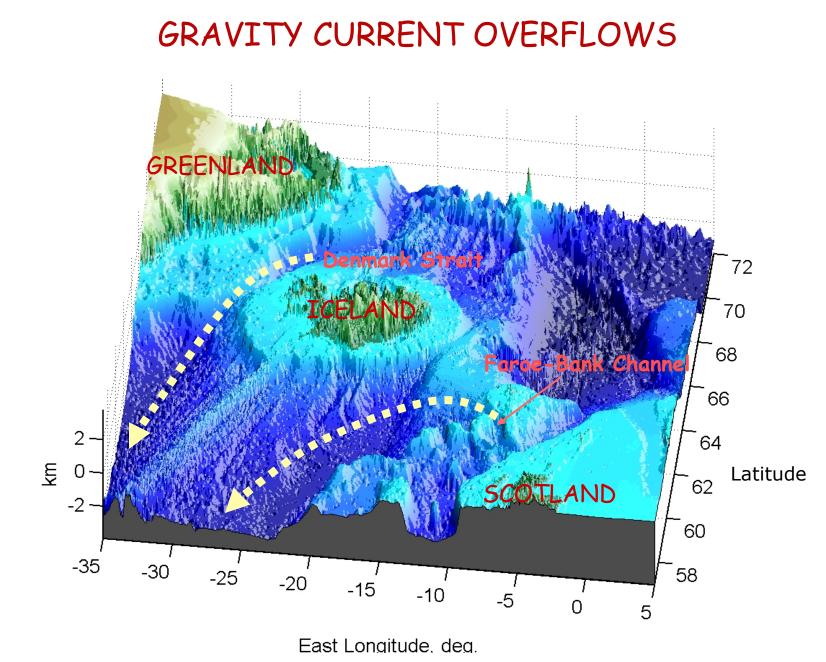

$$v^* = -\frac{\partial \left(A_{ITD}S_{y}\right)}{\partial z} = -\left(\frac{\partial A_{ITD}}{\partial z}S_{y} + A_{ITD}\frac{\partial S_{y}}{\partial z}\right)$$

where S_y is the meridional slope of the isopycnal surfaces and z is the vertical coordinate (positive upwards).

Horizontal-mean v* profiles computed between 20°N and 40°N in the North Pacific
