# Momentum Budget Analysis

$$\frac{\partial u}{\partial t} = fv - \frac{1}{a \cos \phi} \frac{\partial \Phi}{\partial \lambda} - \vec{V} \cdot \nabla u + \frac{uv}{a} \tan \phi + F_{GW,x} + F'$$

[Chapman and Lindzen, 1970]

Advection Term:  $-\vec{V} \cdot \nabla u = -\left(\frac{u}{a \cos \phi} \frac{\partial u}{\partial \lambda} + \frac{v}{a} \frac{\partial u}{\partial \phi} + w \frac{\partial u}{\partial z}\right)$

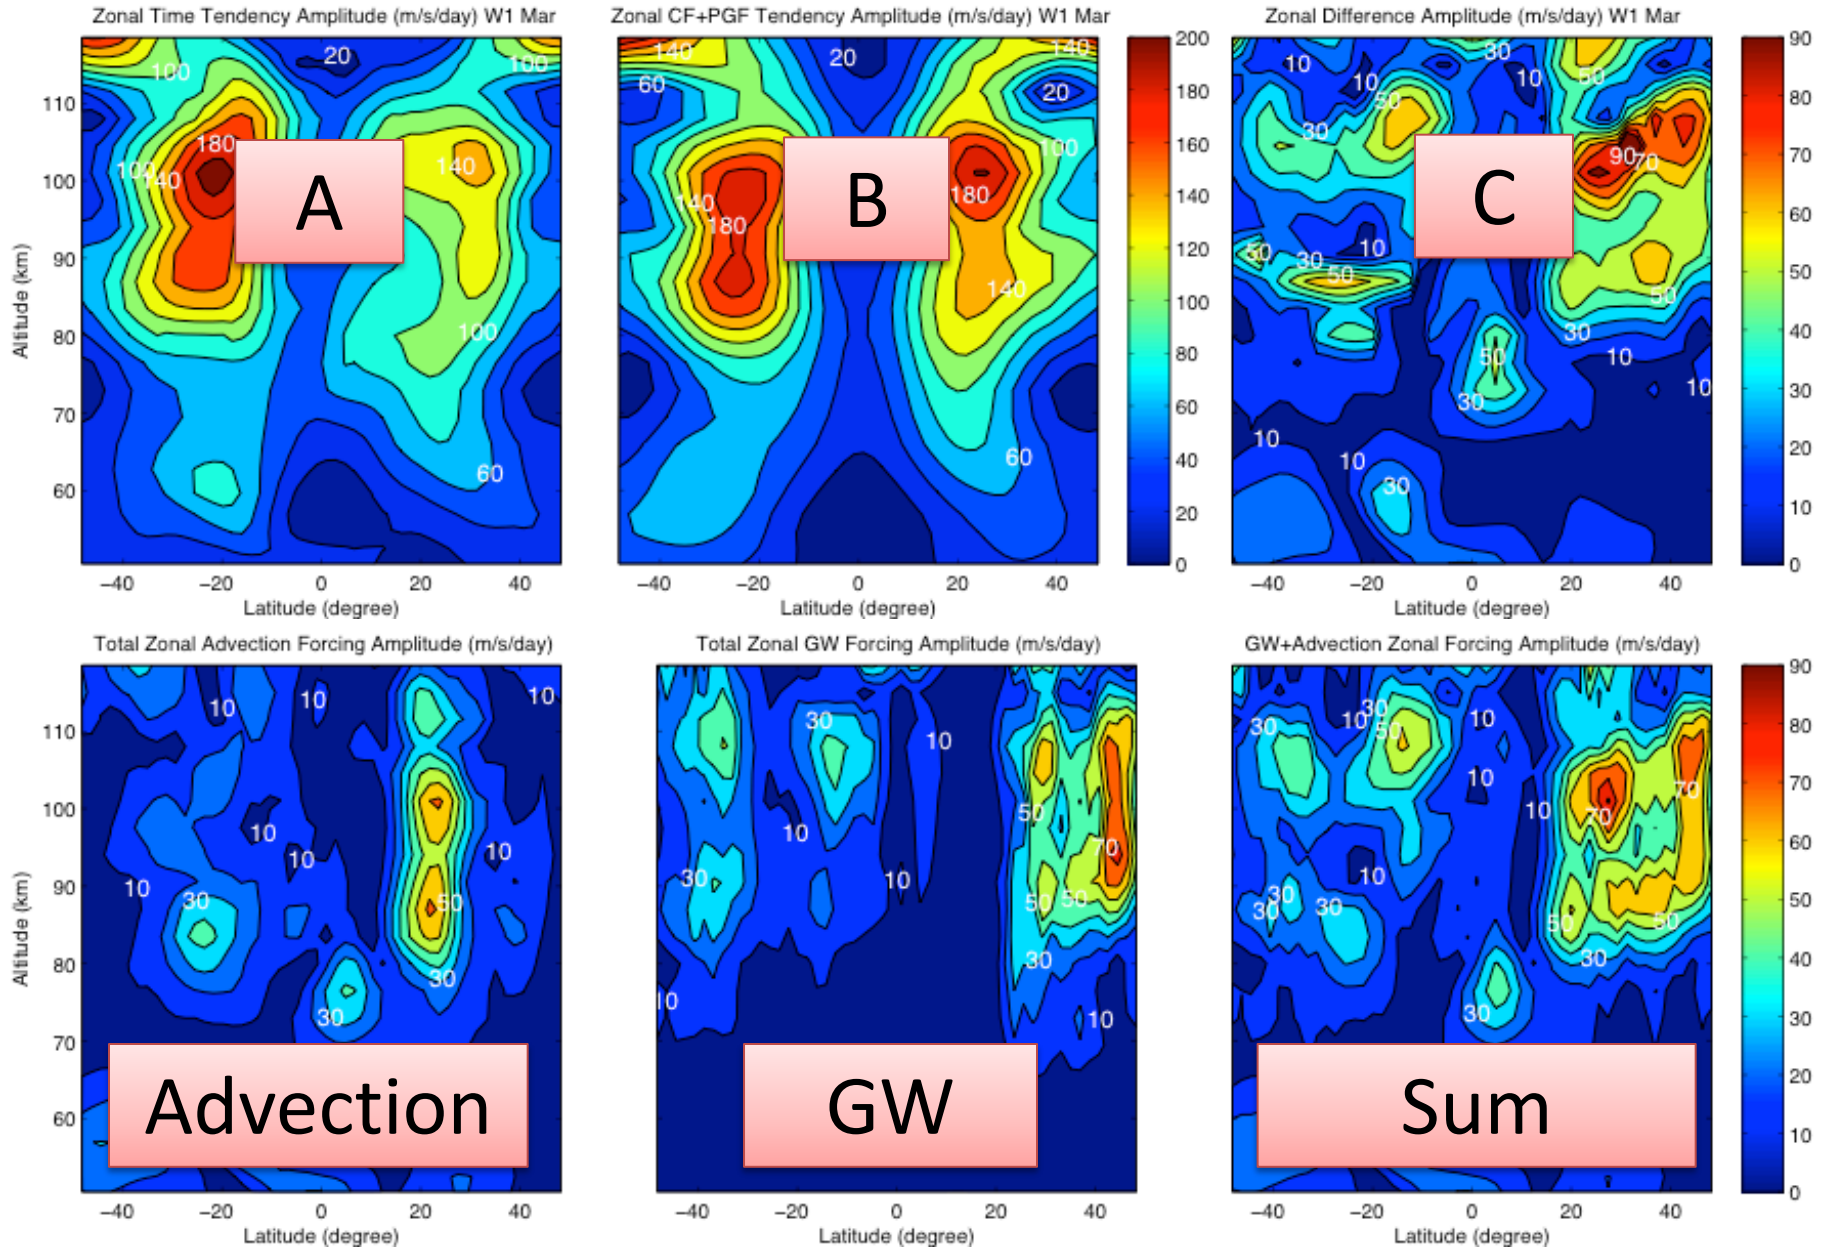

Linear advection Term:

$$\left\{ \begin{array}{l} u = \bar{u} + u' \\ v = \bar{v} + v' \\ w = \bar{w} + w' \end{array} \right\} \Rightarrow F_{LinAd,x} = -\left(\frac{v'}{a} \frac{\partial \bar{u}}{\partial \phi} + w' \frac{\partial \bar{u}}{\partial z}\right) - \left(\frac{\bar{u}}{a \cos \phi} \frac{\partial u'}{\partial \lambda} + \frac{\bar{v}}{a} \frac{\partial u'}{\partial \phi} + \bar{w} \frac{\partial u'}{\partial z}\right)$$

## Amplitude of Time Tendency (Zonal Wind)

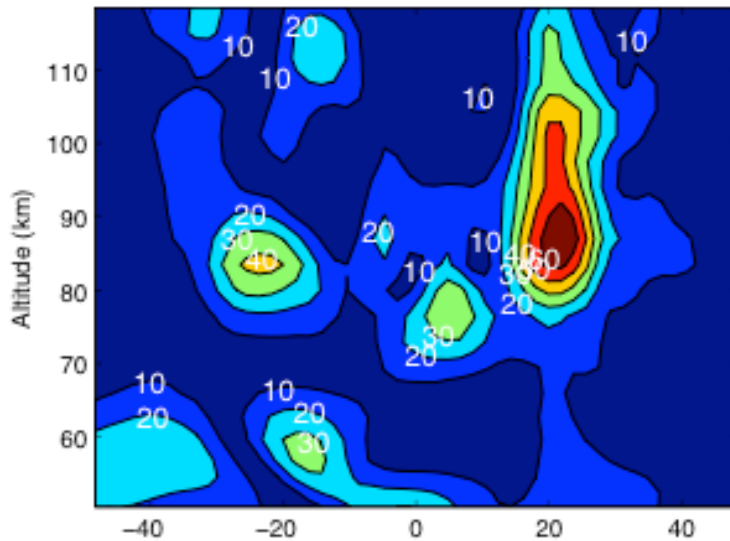

# Amplitude of Time Tendency (Meridional Wind)

# Which advection is more dominant?

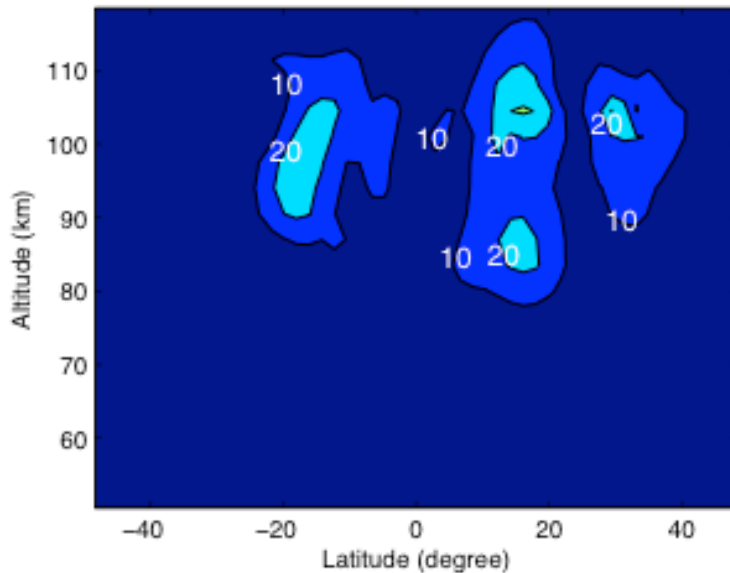

(a) Linear Zonal Advection Amplitude (m/s/day) W1

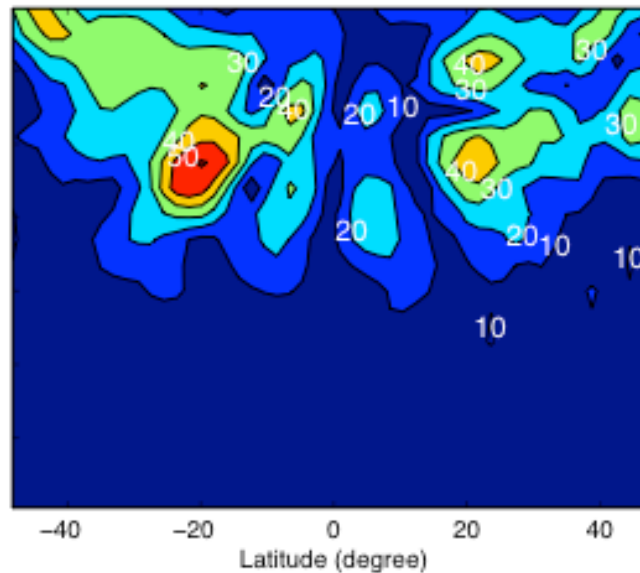

(b) Nonlinear Zonal Advection Amplitude (m/s/day) W1

(c) Linear Meridional Advection Amplitude (m/s/day) W1

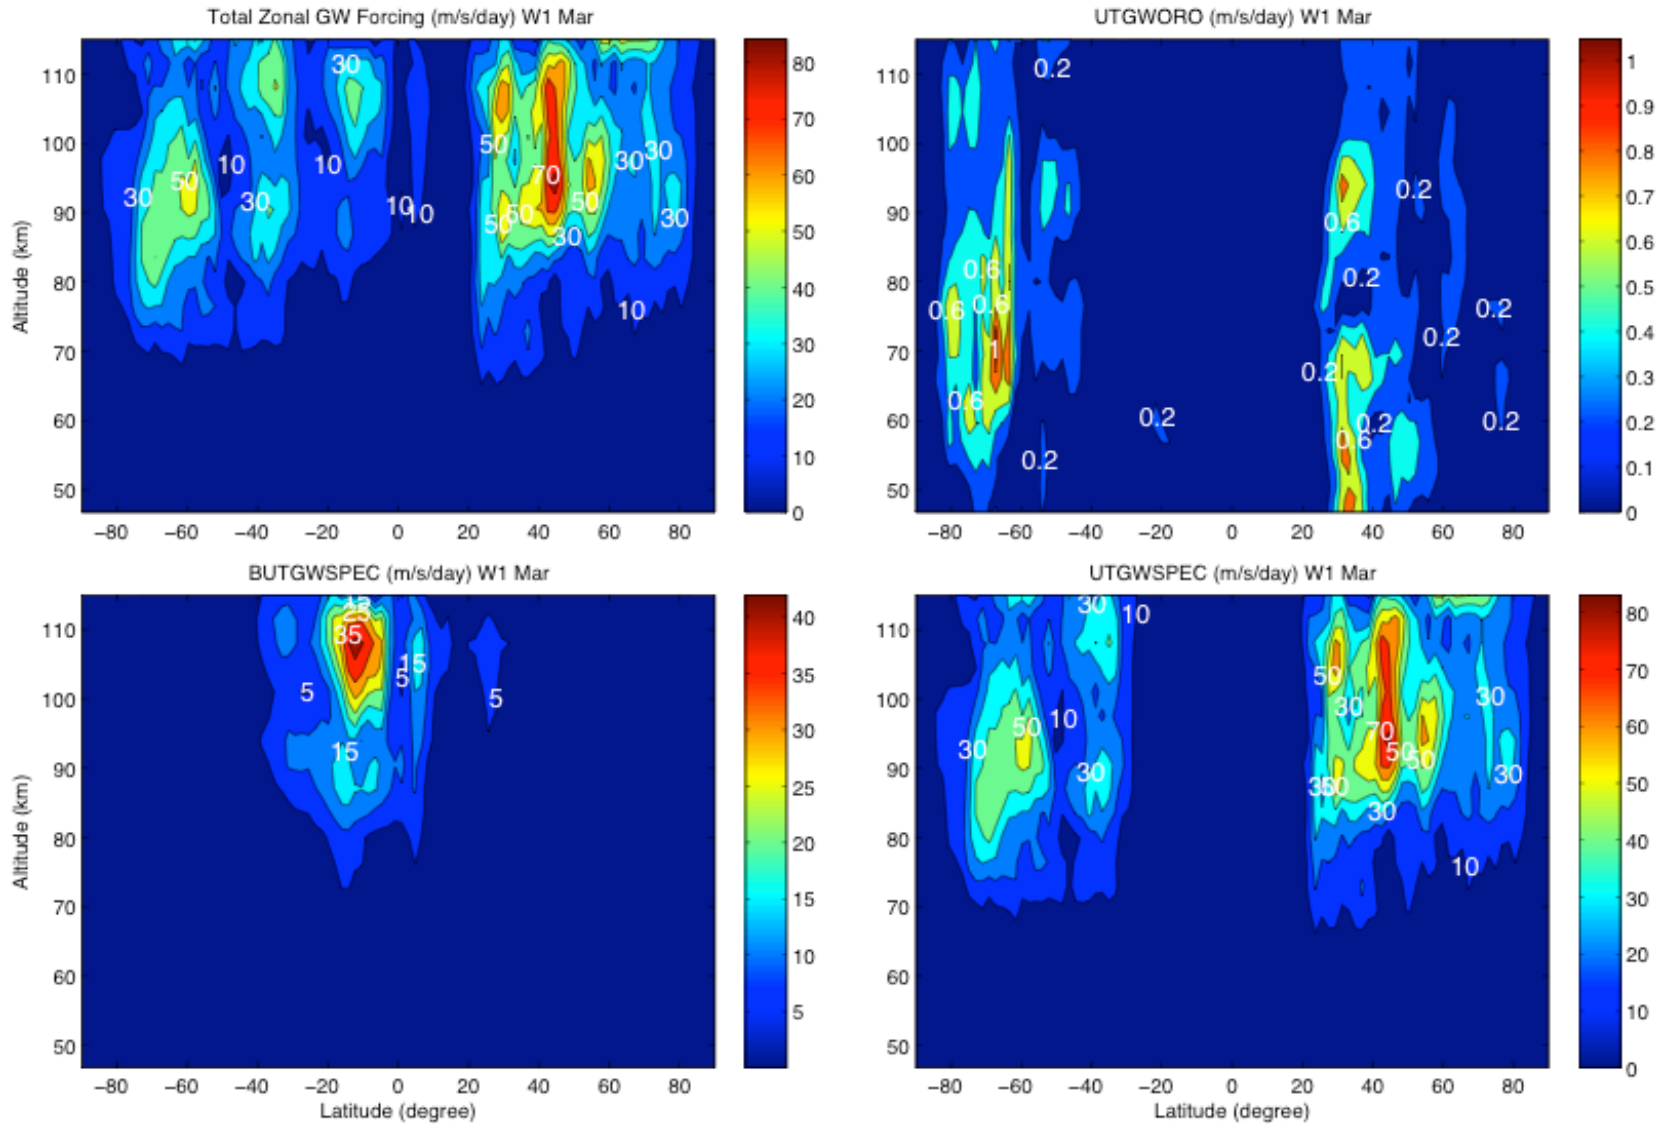

(d) Nonlinear Meridional Advection Amplitude (m/s/day) W1

# GW sources

Frontogenesis > Convection > Orography

# Equivalent Rayleigh Friction

[Miyahara and Forbes, 1991]

$$\frac{\partial u'}{\partial t} = F'$$

$$u' = \hat{u}(t)e^{i(\omega t - s\lambda)} = a(t)e^{i(-\varphi(t))}e^{i(\omega t - s\lambda)} = a(t)e^{i(\omega t - s\lambda - \varphi(t))}$$

$$F' = \hat{F}_u(t)e^{i(\omega t - s\lambda)}$$

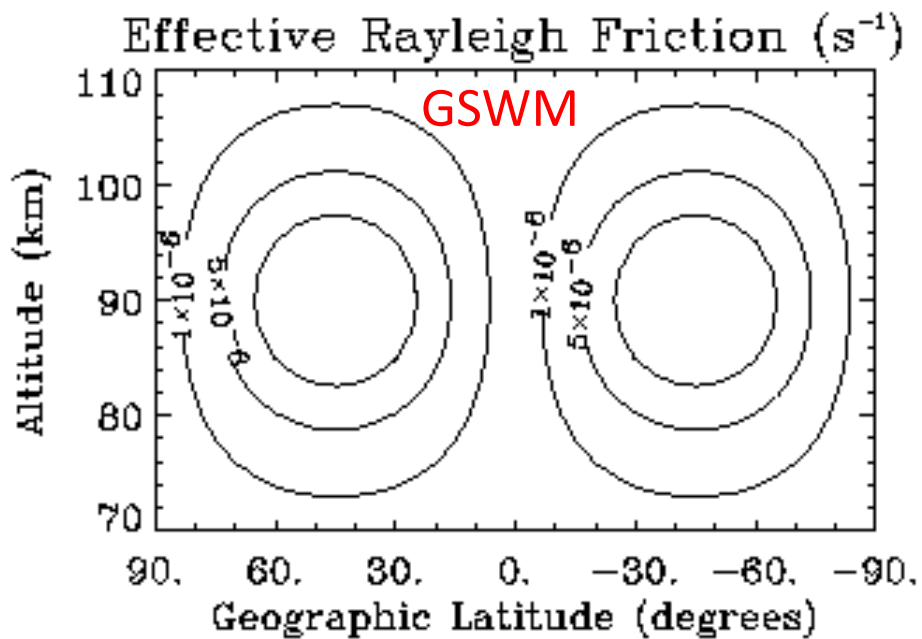

Define the Equivalent Rayleigh Friction as:

$$ERF = -\frac{\hat{F}_u}{\hat{u}} = -\frac{\frac{\partial a(t)}{\partial t}}{a(t)} - i\left(\omega - \frac{\partial \varphi(t)}{\partial t}\right)$$

Real Part of ERF determines the amplitude change and imaginary part determines the phase change.

$real(ERF) > 0$  : Amplitude      Decrease

$imag(ERF) < 0$  : Phase      Advance

[Hagan et al., 1995]

# Frontogenesis-GW drag to mean flow

Units: m/s/day

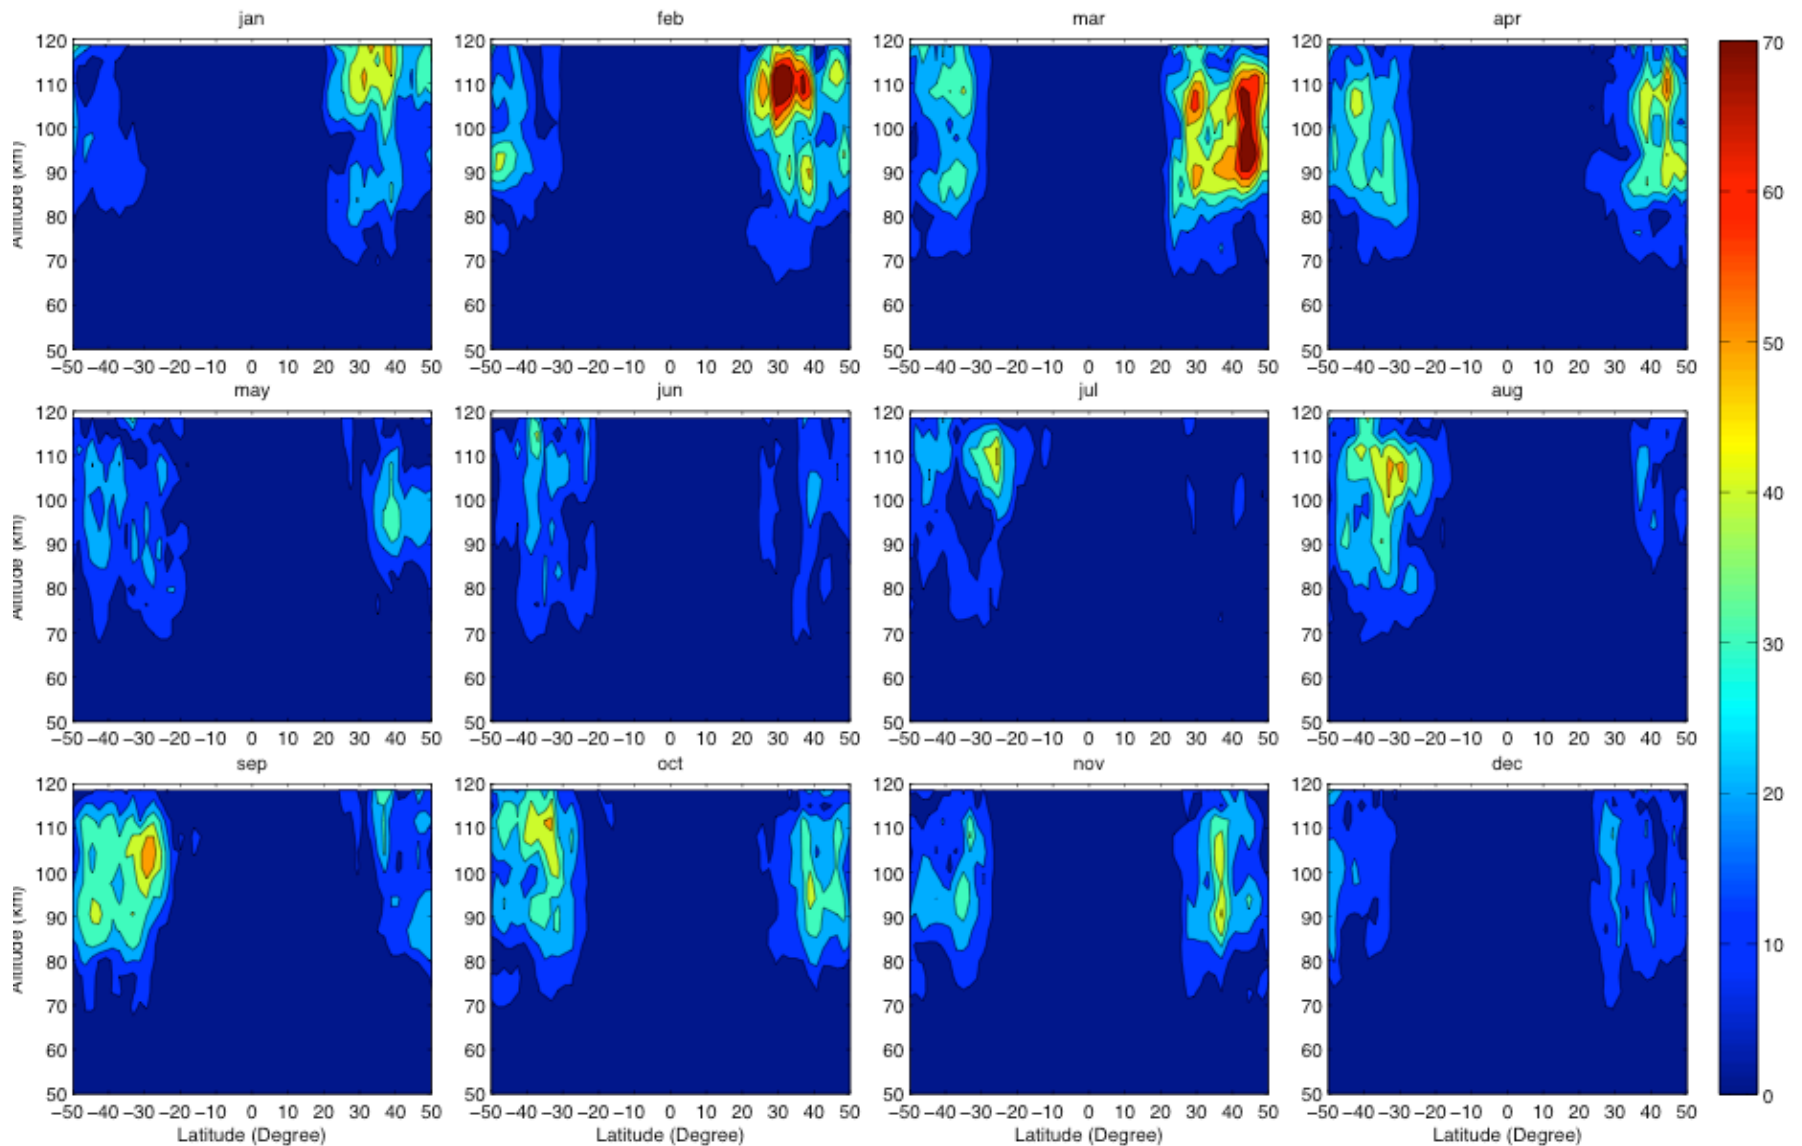

# Convection-GW drag to mean flow

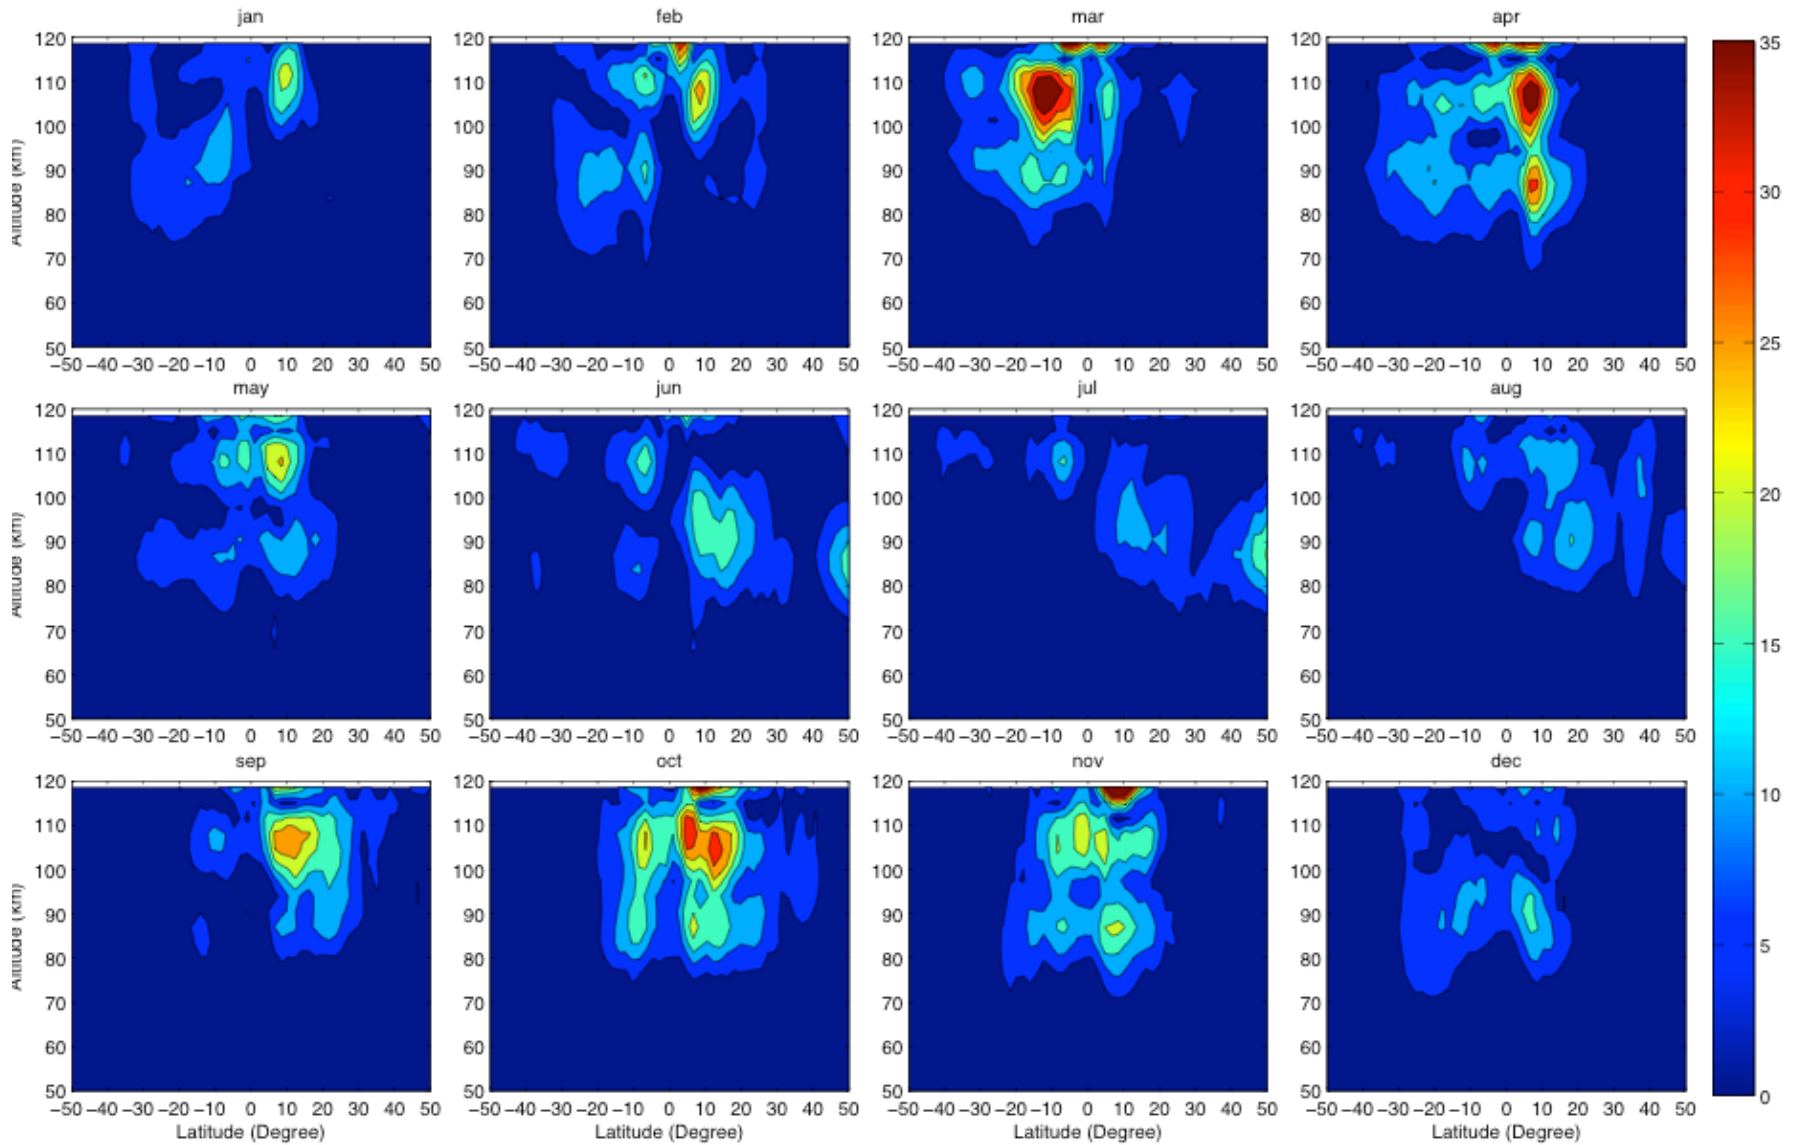

Units: m/s/day

# Frontogenesis-GW drag to the migrating diurnal tide

# Convection-GW drag to the migrating diurnal tide

# Conclusions

- Advection and GW drag are two most important terms to account for the momentum budget of the migrating diurnal tide.
- For zonal wind, the magnitudes of linear advection and GW forcing are comparable while for the meridional wind, advection is more dominant.
- GW drag always damps the tide and advances its phase.
- For the zonal wind, GW is most responsible to change the amplitude and linear advection to the change of tidal phase. In meridional wind, nonlinear advection is the most significant factor to change both amplitude and phase of tide.
- GW drag is strongly modulated by the migrating diurnal tide, the seasonal variation of GW forcing is more like a feedback to that of the tidal modulation, rather than a cause for the seasonal variation of tide.

A photograph of a sky filled with a dense, repetitive pattern of small, white, cloud-like shapes that resemble the ridges of a fingerprint. The pattern is most prominent in the lower half of the image and fades into a clear blue sky at the top. The overall effect is a complex, textured background.

Thank you!
