

Effects of agriculture on surface energy partitioning and climate over the continental U.S. using WRF-CLM

Yaqiong Lu¹, Jiming Jin², & Lara M. Kueppers^{1,3}

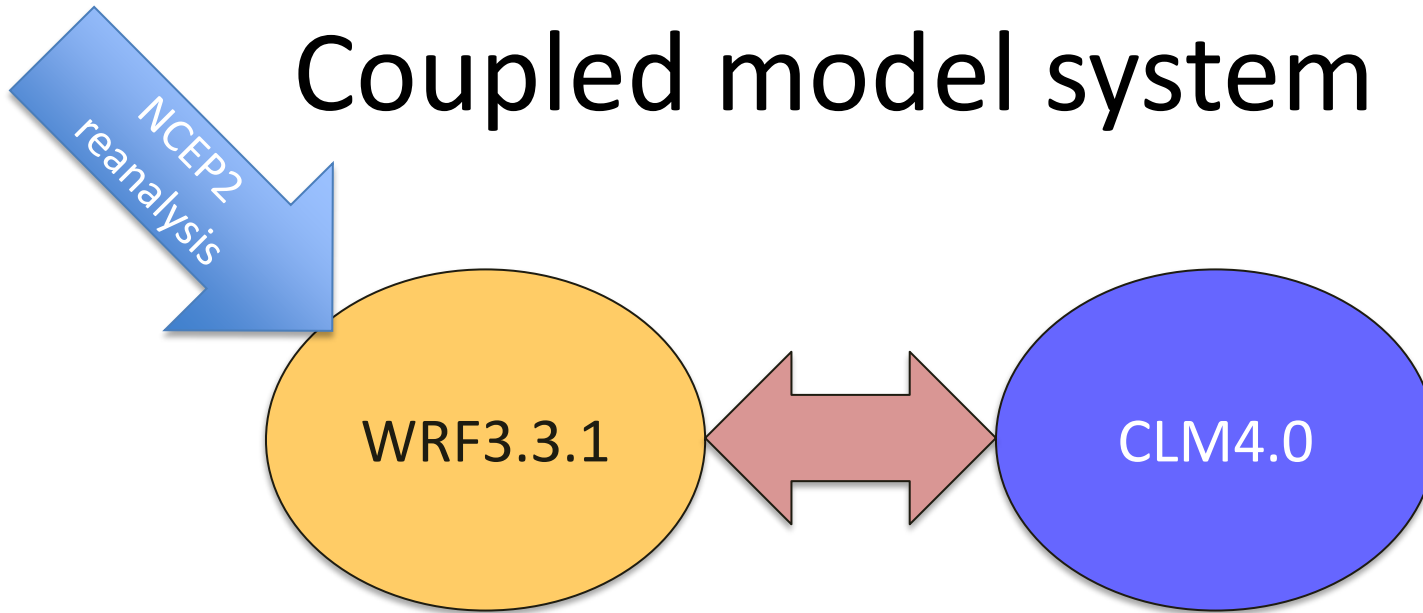

¹UC Merced, ²Utah State University, ³LBNL

With elements of CLM4CNCrop code from Sam Levis, NCAR

Why a regional climate-crop model?

- Agriculture a large footprint in U.S. (and elsewhere) but spatially heterogeneous
- Crops sensitive to climate variability
- Crop systems have large potential biogeophysical climate influence
 - Leaf area index (m^2 leaves/ m^2 ground)
 - Irrigation
- (Ignoring biogeochemical feedbacks at regional scale...for now)

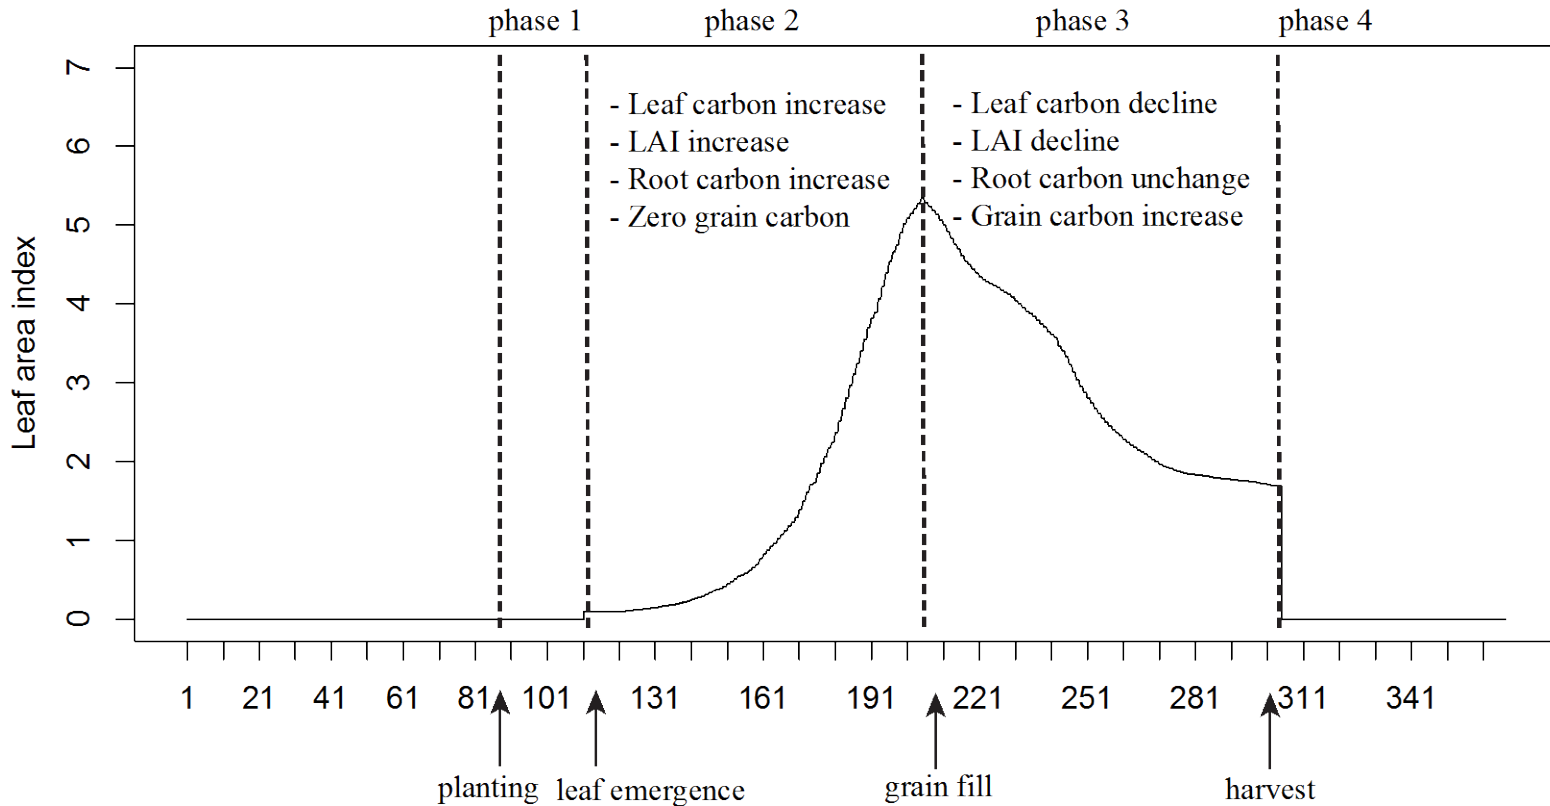

Coupled model system

Resolution	<ul style="list-style-type: none">• 50km horizontal, 25 vertical layers
Domain	<ul style="list-style-type: none">• 109 south north and 129 west east grid cells over U.S.
Run times	<ul style="list-style-type: none">• 5 years: 2002-2006, discarding the first 2 years• 10 years: 2002-2011, discarding the first 2 years
WRF schemes	<ul style="list-style-type: none">• MYNN boundary layer scheme• CAM longwave/shortwave radiation scheme• New Grell cumulus scheme• Thompson microphysics scheme

(earlier versions: Subin et al. 2011; Lu & Kueppers 2012)

Dynamic crop leaf area phenology

Similar to CLMCNCrop (Levis et al. 2012), *except*

Planting GDD accumulated over fewer years (5 not 20)

Harvest is $1.5 * \text{GDD}$ for maturity so crop dries before harvest (Nielsen 2011)

Modified C allocation to better capture water stress effects

Dynamic crop irrigation

- Irrigation applied after leaf emergence
- ...and when root water stress increases OR when leaf temp $> 35^{\circ}\text{C}$
- Water applied as rain 0.0002 mm/s (in range of 4-20 gal/min/acre of current systems)

Irrigation distribution

Observed pixel % “equipped for irrigation”

Irrigation percentage (%)

(Siebert, Doll et al. 2005)

Model average irrigation amount

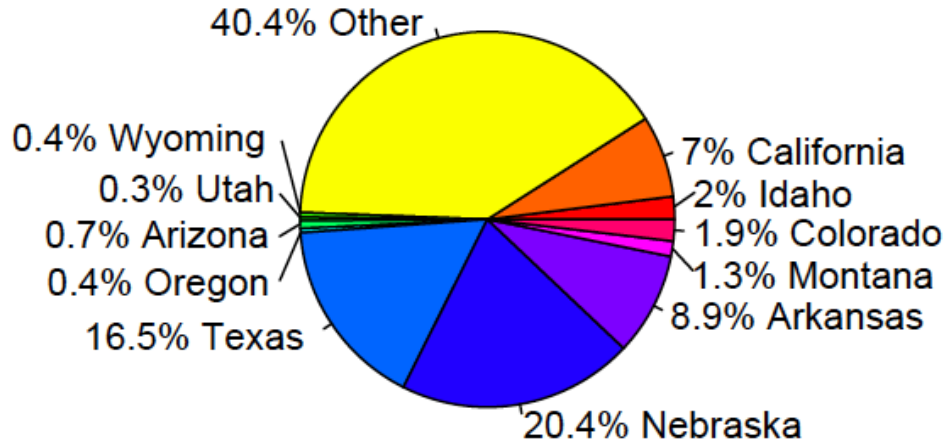

Irrigation water (Mgal/day)

(Simulated by WRF-CLM for 2004-2006)

Model vs observed 2005 irrigation

Model (143,000 Mgal/day)

2004-2006 values 113,000-149,000 Mgal/d

USGS (128,000 Mgal/day)

2000 withdrawals est 137,000 Mgal/d

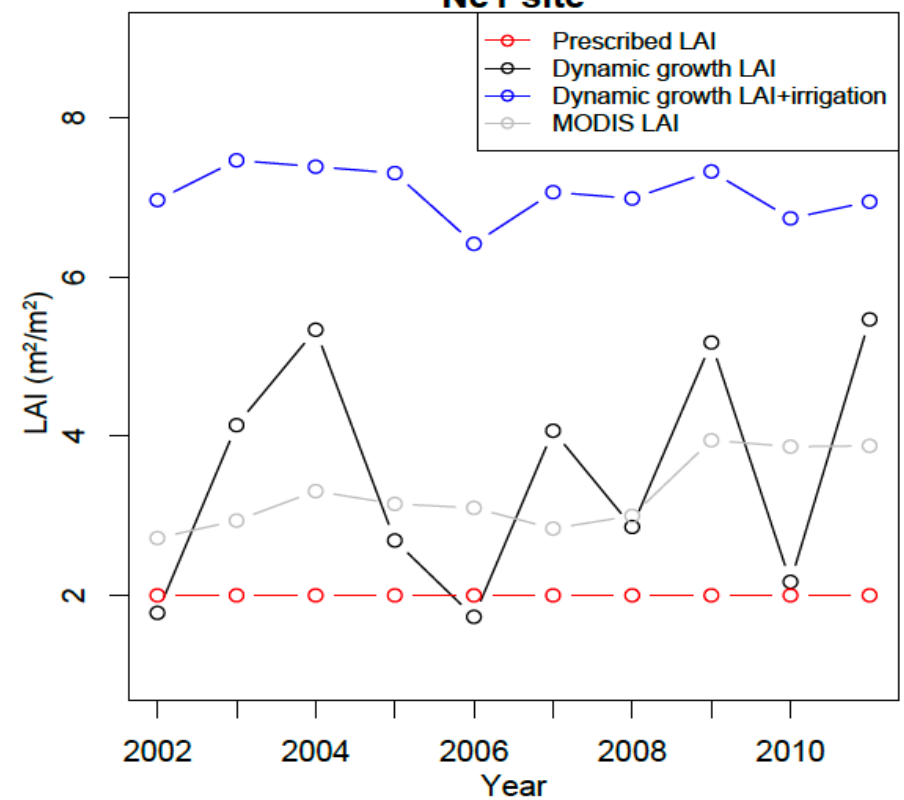

(<http://ga.water.usgs.gov/edu/wuir.html>)

Model vs observations for peak LAI

ARM (not irrigated, Oklahoma)

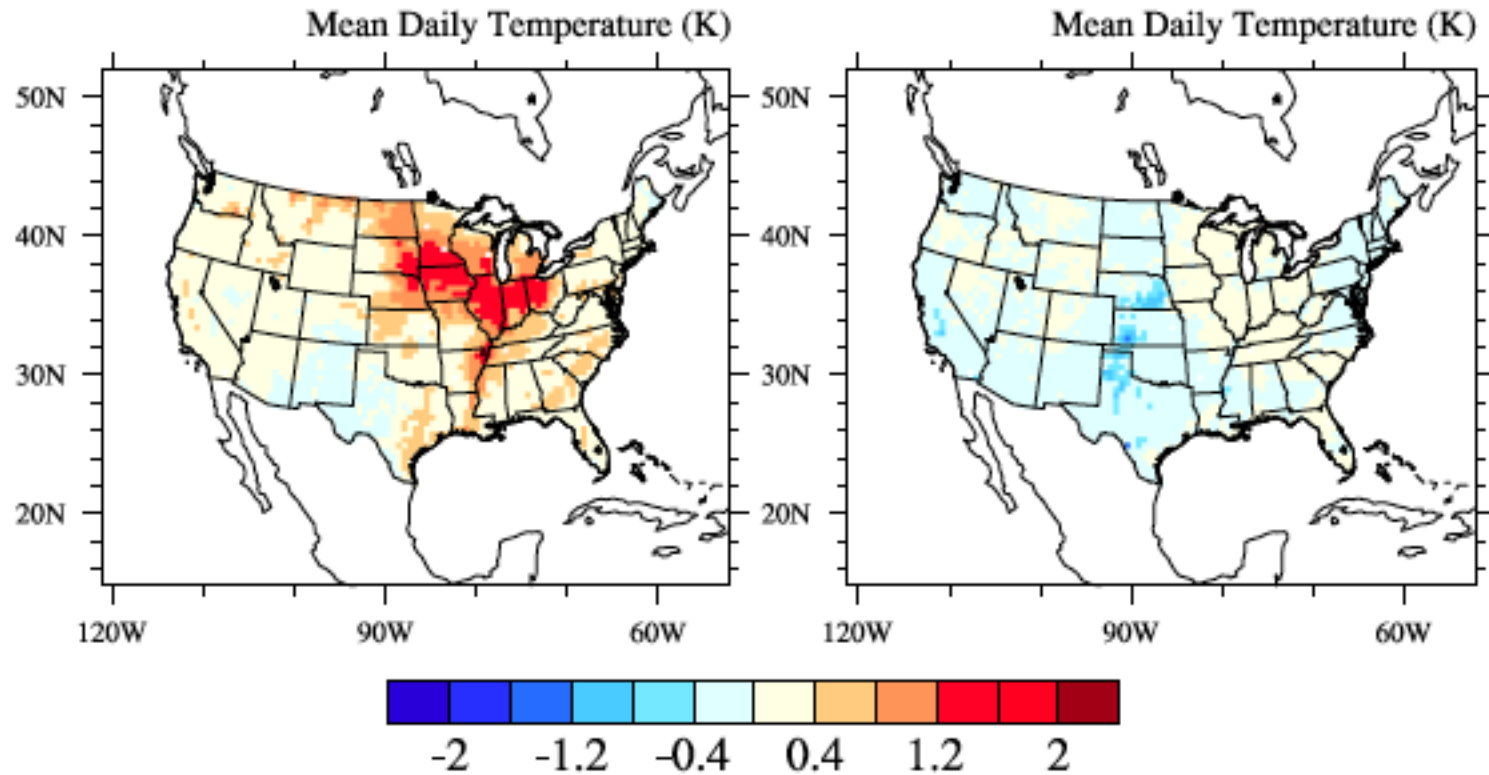

Ne1 (irrigated, Nebraska)

Dynamic crop and irrigation cool

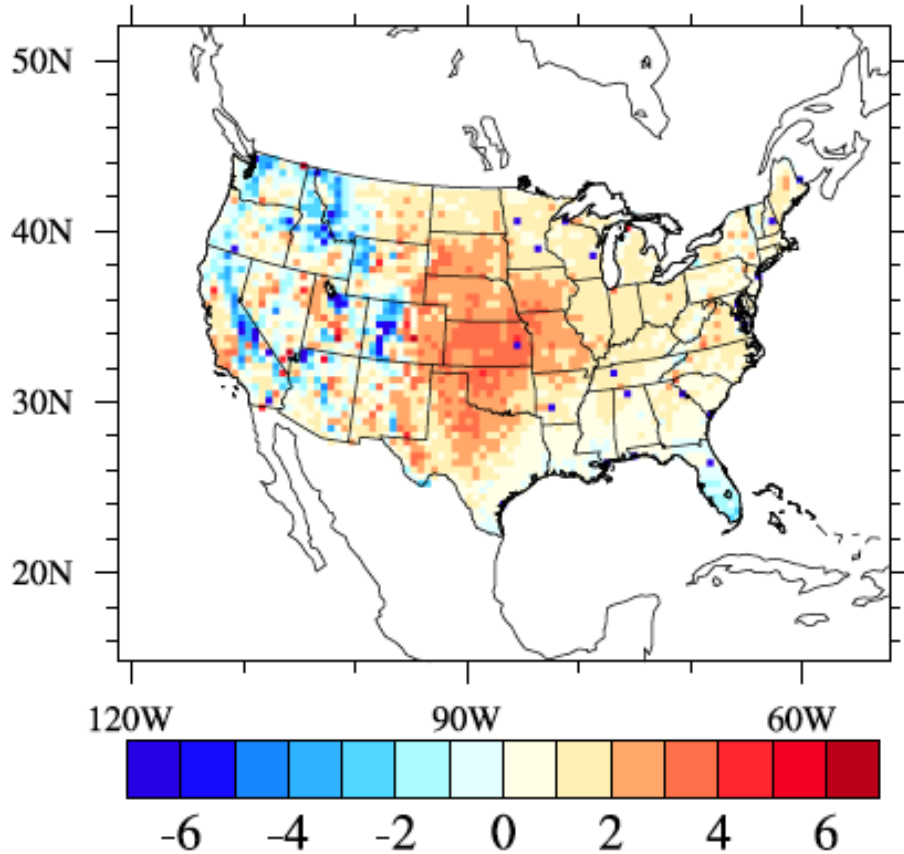

Prescribed – dynamic LAI

Dynamic irrigation – dynamic no irrigation

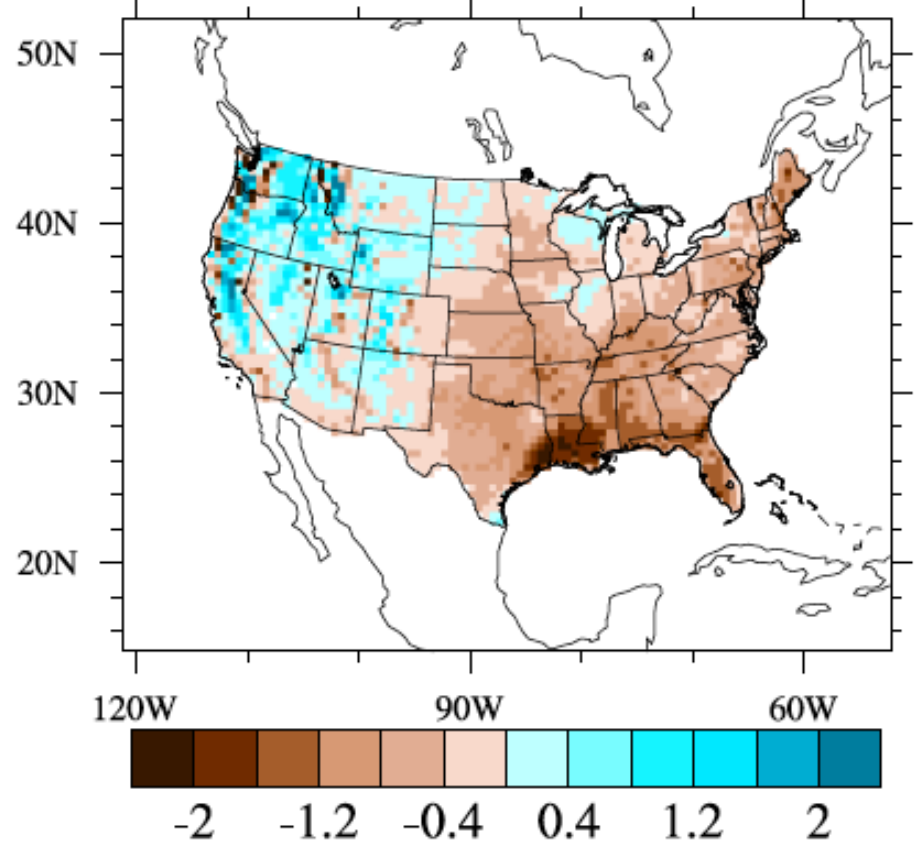

WRF3.3-CLM4CropIrr vs PRISM obs

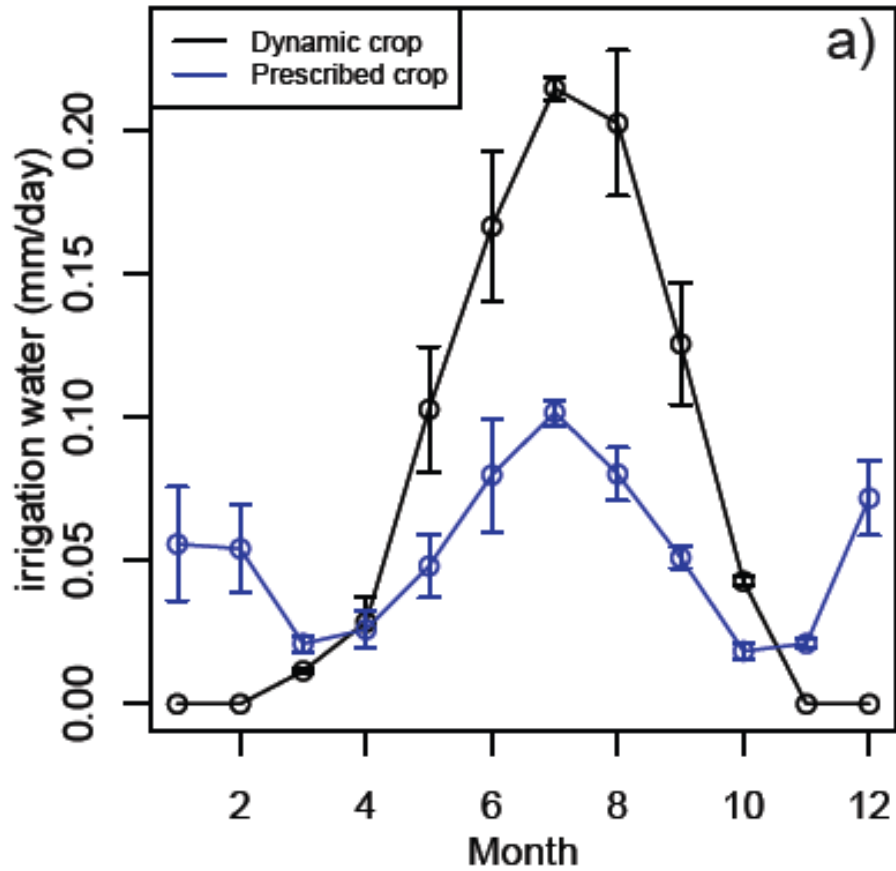

Mean Daily Temperature (K)

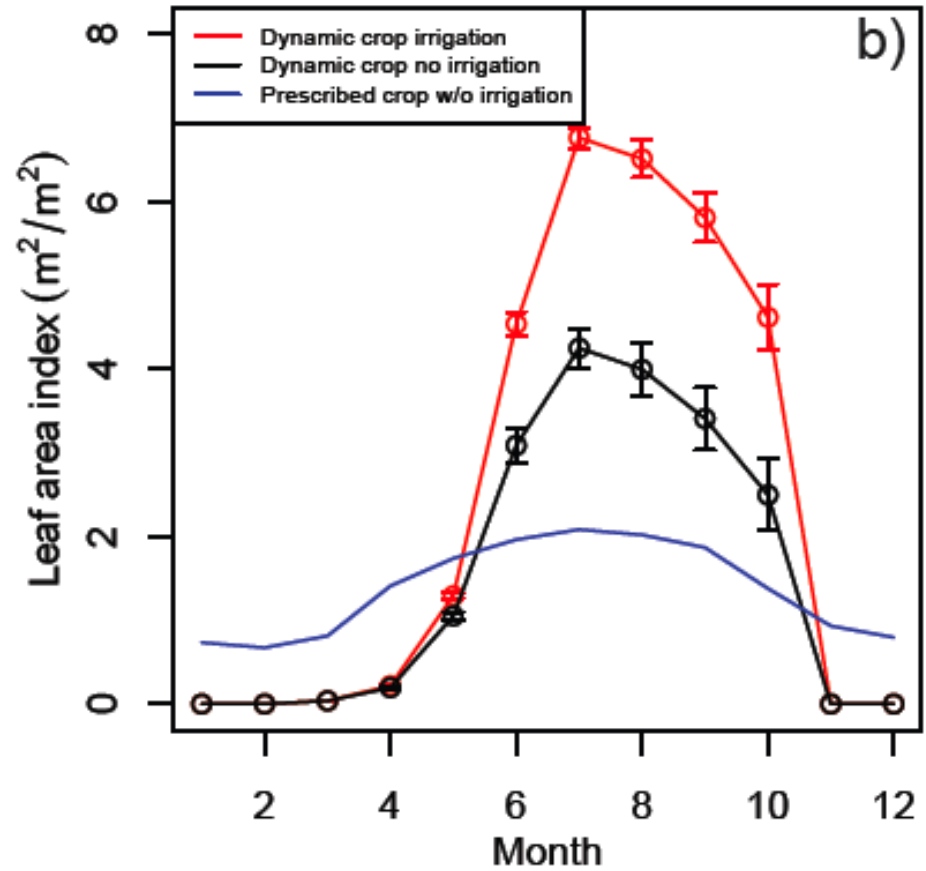

Precipitation (mm/day)

LAI and irrigation water synergies

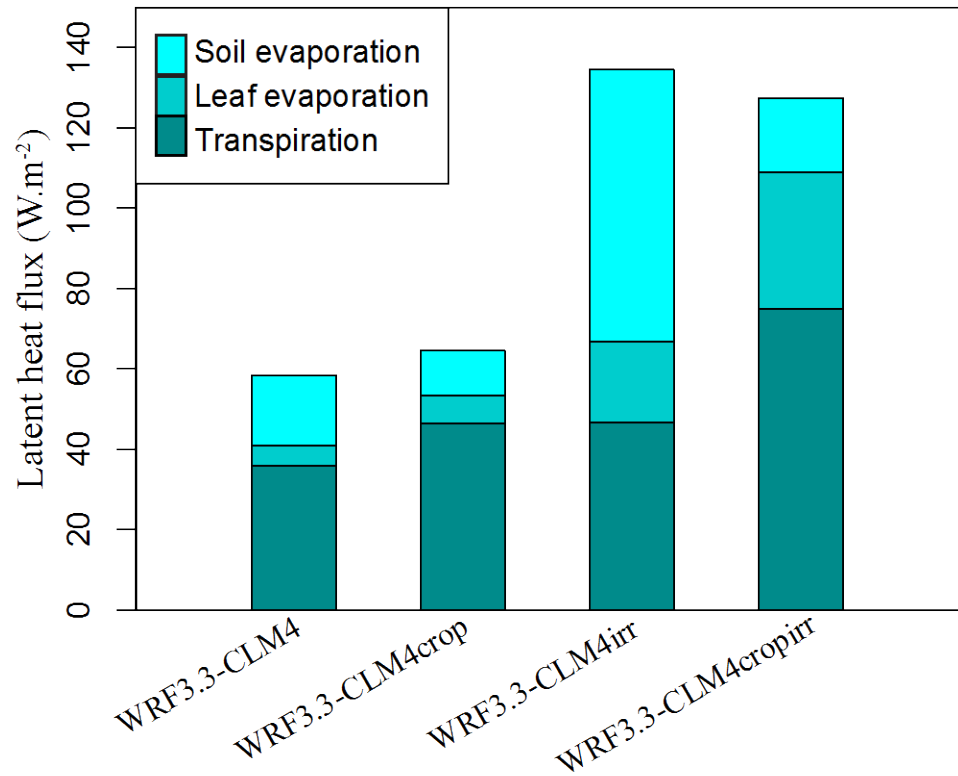

Dynamic LAI model uses more irrigation water

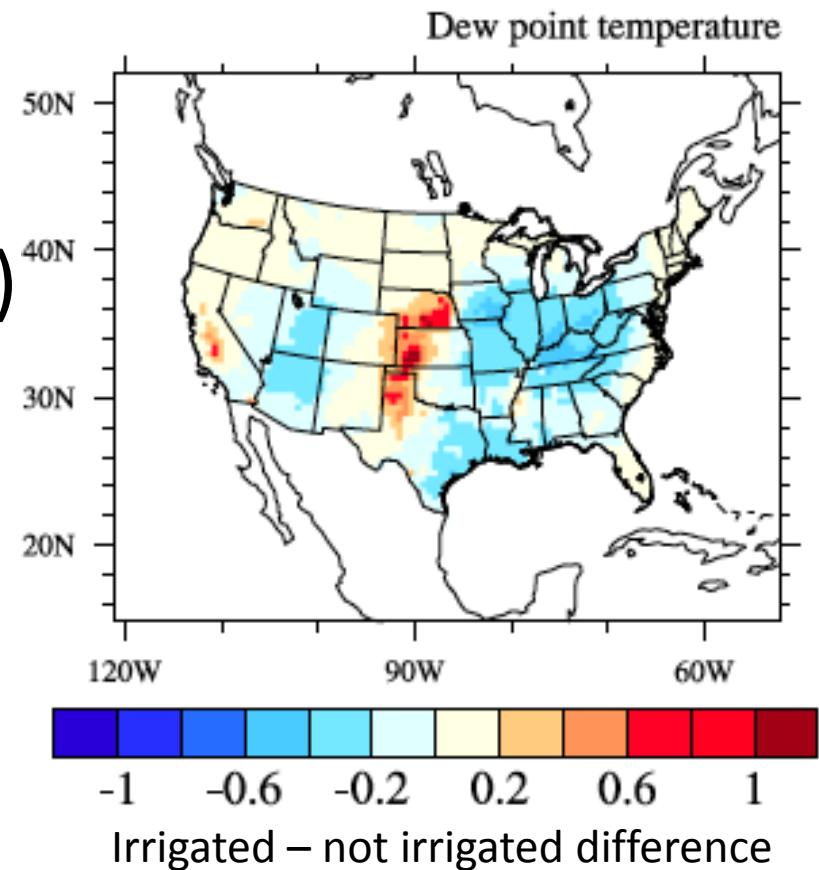

Irrigated crop model has greater LAI

Irrigation without dynamic LAI results in too-high soil evaporation

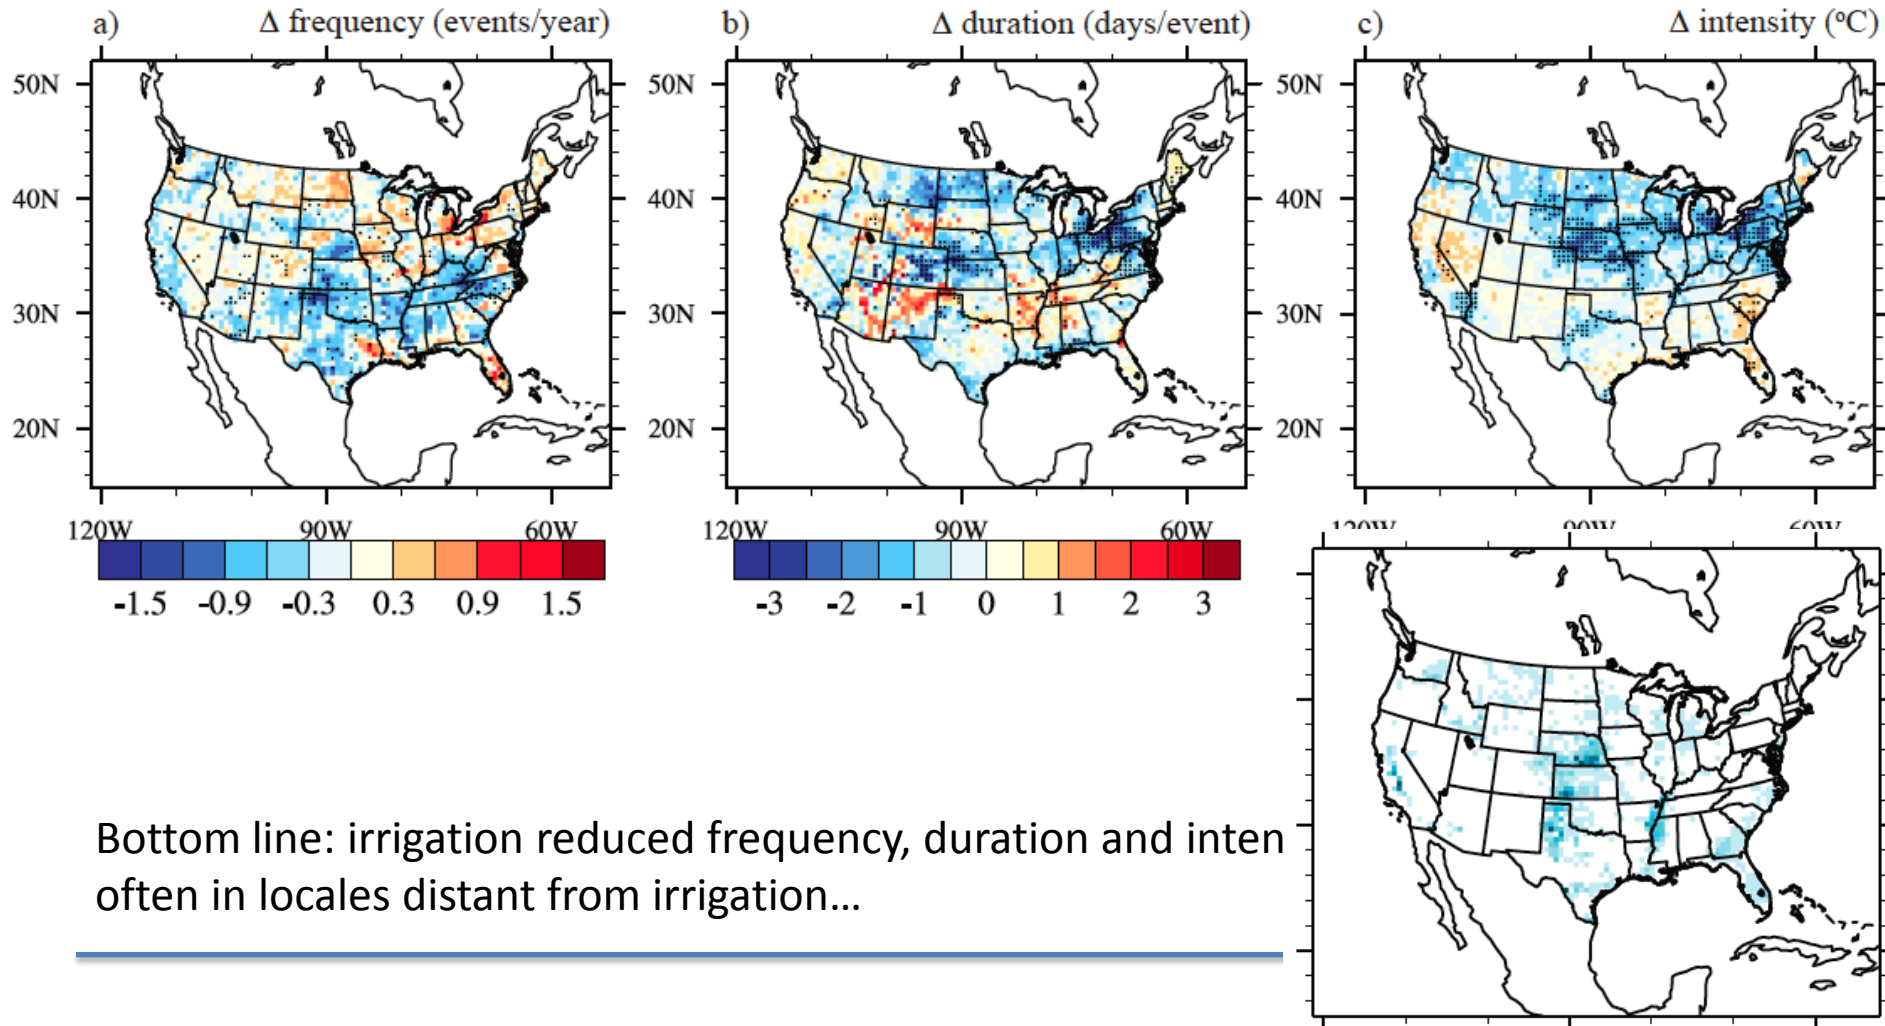

Can irrigation exacerbate heat waves?

- Irrigation increases dew point temperature too
- Heat index (Schoen 2005) includes both T and T_d
- Increased T_d can exacerbate heat wave impacts

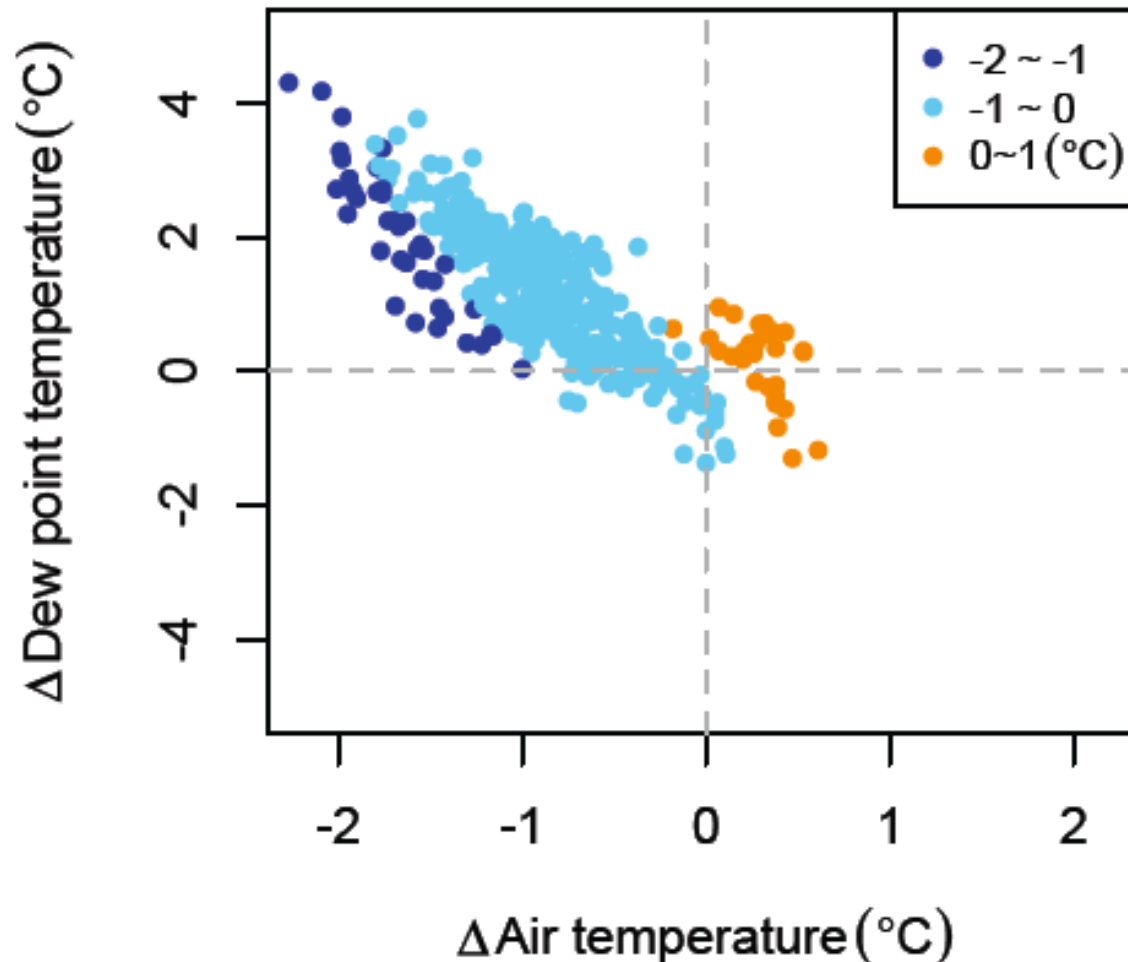

Irrigation effects on heat waves

Irrigated – not irrigated differences

Can irrigation increase heat wave intensity? Only where air T increased.

CROPIRR-CROP heat index

Next steps

- Convert generic “crop” to real crops (corn, wheat, soy, sorghum, cotton, other?) and validate yields (irrigated and non) – transition to new CLM4.5CNCrop?
- Longer historical simulations to look at county yield *variability* relative to USDA statistics
- Force CLM4CNCrop (with all crops) with mid-century climate scenarios
- Sensitivity studies of potential farmer adaptations
