Two types of fast glacier movement and acceleration

Jakobshavn Isbræ, Western Greenland —

- Spatial acceleration caused by existence of a deep trough in the subglacial topography
- Continuously fast-flowing

Bering Glacier System, Alaska

- Acceleration (in time) caused by internal dynamics of the glacier – surge cycle
- Quasi-cyclic oscillation between phases of slow and fast movement

Complications

Jakobshavn Isbræ, Western Greenland -

- Rapid retreat and acceleration since 1997, accompanied by surface lowering
- The main cause of fast flow is still the trough
- Reversible IF fjord-glacier cycle
- Probably irreversible if warming at front (ice-ocean interaction)

Bering Glacier System, Alaska

Surge cycles are underlain by a trend of glacial retreat

This talk is not about the complications !

- (1) Surges occur repeatedly.
- (2) Quiescent phase is fairly constant (10-100 yrs).
- (3) Surge phase is short (1-several years).
- (4) Surge phase: ice speed 10-100 times the normal speed, ice displaced rapidly from uplacier reservoir to downglacier receiving area, large elevation changes in ice surface (10-100m).
- (5) Quiescent phase: low ice speed, ice builds up in reservoir area.

- (a) Beginning surge stage: Early summer 1993, few crevasse fields
- (b) Mature surge stage: after surge reached terminus in 1993, and summer 1994
- (c) Late surge stage: after onset of water outburst during August 1994, and continuing through August 1995

Note: Bagley Ice Field surges as well, mostly the eastern Bagley. Surge extended 15km into western Bagley. Steller Glacier pulses. References: Herzfeld 1998 (BeringBook), Herzfeld and Mayer J. Glaciol. 1997

Project Objectives: BERING Glacier Surge RAPID (NSF)

Background

- The cryosphere changes at an alarming rate.
- ▶ Most changes in glaciers and ice sheets are driven by glacial acceleration.
- Surges are one of three only three forms of acceleration and the least studied one (surges are relatively rare but important).
- The Bering-Bagley Glacier System is a large, complex glacier system (largest glacier outside of Greenland and Antarctic Ice Sheets); but most glaciologic knowledge on surges is based on small glaciers.

Objectives

- Observation: Systematic collection of airborne videographic, photographic, GPS and laser altimeter data
- Analysis: Elevation change, crevassing, hydrologic changes, surge progression
- Parameterization: Derivation of parameters that can be used in ice-dynamic modeling of a surge
- ► Transfer: Prototype of a surge in large, complex glacier system

What is spatial surface roughness?

a derivative of (micro)topography
 → characterization of spatial behavior

Why do we need spatial surface roughness?

- sub-scale information for satellite measurements
- indicator variable for other, harder to observe processes
- parameterization of sub-scale features or processes

Ute C. Herzfeld^(1,2,3) Thomas Trantow^(3,1), Brian McDonald⁽ Insights on Ice-Dynamic Modeling from Observations of Fast

Definition of Vario Functions

 $V = \{(x, z) \text{ with } x = (x_1, x_2) \in \mathcal{D} \text{ and } z = z(x)\} \subseteq \mathcal{R}^3$

discrete-surface case or

$$V = \{(x, z) \text{ with } x \in \mathcal{D} \text{ and } z = z(x)\} \subseteq \mathcal{R}^2$$

discrete-profile case

Define the first-order vario function v_1

$$v_1(h) = \frac{1}{2n} \sum_{i=1}^n [z(x_i) - z(x_i + h)]^2$$

with $(x_i, z(x_i)), (x_i + h, z(x_i + h)) \in D$ and *n* the number of pairs separated by *h*.

Ute C. Herzfeld^(1,2,3) Thomas Trantow^(3,1), Brian McDonald Insights on Ice-Dynamic Modeling from Observations of Fast G

Higher-Order Vario Functions

The first-order vario-function set is

$$V_1 = \{(h, v_1(h))\} = \underline{v}(V_0)$$

Then: get V_2 from V_1 in the same way you get V_1 from V_0 . The second-order vario function is also called varvar function.

Recursively, the vario function set of order i + 1 is defined by

$$V_{i+1} = \underline{v}(V_i)$$

for $i \in \mathcal{N}_0$.

Ute C. Herzfeld^(1,2,3) Thomas Trantow^(3,1), Brian McDonald⁽ Insights on Ice-Dynamic Modeling from Observations of Fast C

Geostatistical Classification Parameters

significance parameters:

slope parameter:

$$\mathfrak{p}1=rac{\gamma_{ extsf{max}_1}-\gamma_{ extsf{min}_1}}{h_{ extsf{min}_1}-h_{ extsf{max}_1}}$$

relative significance parameter:

$$p2 = \frac{\gamma_{max_1} - \gamma_{min_1}}{\gamma_{max_1}}$$

pond – maximum vario value mindist – distance to first min after first max

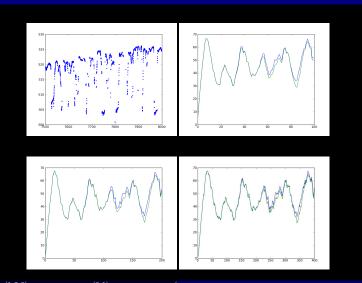

$$avgspac = \frac{1}{n} \sum_{i=1}^{n} \frac{1}{i} h_{min_i}$$

typically for n = 3 or n = 4

Elevation-change determination

- Elevation change -40 to -70 m in reservoir area, +20-40m in Tashalich Arm (receiving area)
- Sudden mass transfer typical of a surge

Elevation change determined from laser altimeter data collected by C. Larsen, University Alaska Fairbanks, 2010,

under NASA Operation IceBridge, and by U.C Herzfeld, Sept. 2011, as part of NSF project. (Herzfeld et al.,

Applications:

- Segmentation of Bering–Bagley System into deformation provinces
- Understanding of surge phenomenon
- Parameterization of fracturing in glaciers
 - subgrid modeling
- Parameterization of deformation processes
 - modeling glacial dynamics
- Transfer of dynamic processes to understand acceleration and dynamic thinning in other glaciers, e.g. Greenland outlet glaciers

Towards Modeling Surges in Complex Glacier Systems

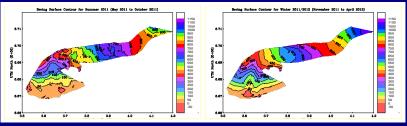

Questions:

- What makes a glacier a surge-type glacier?
- What causes and controls surges?
- What initiates a surge?
- Environmental setting or special physics?
- Can the surge phenomenon be explained by standard physics (Glen's flow law and using full Stokes)?

The following experiments use Glen's flow law and full Stokes and employ Elmer Ice. (Model experiments by Tom Trantow).

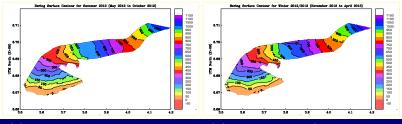

Then compare modeled variables and observations: What can the model explain? What can it not explain?
