

Comparison of Organic Aerosol (OA) treatments in CESM: Difference in source contribution and lifetimes

Alma Hodzic, Simone Tilmes, Francis Vitt,
Manish Shrivastava, Louisa Emmons, Christoph Knote

GOALS:

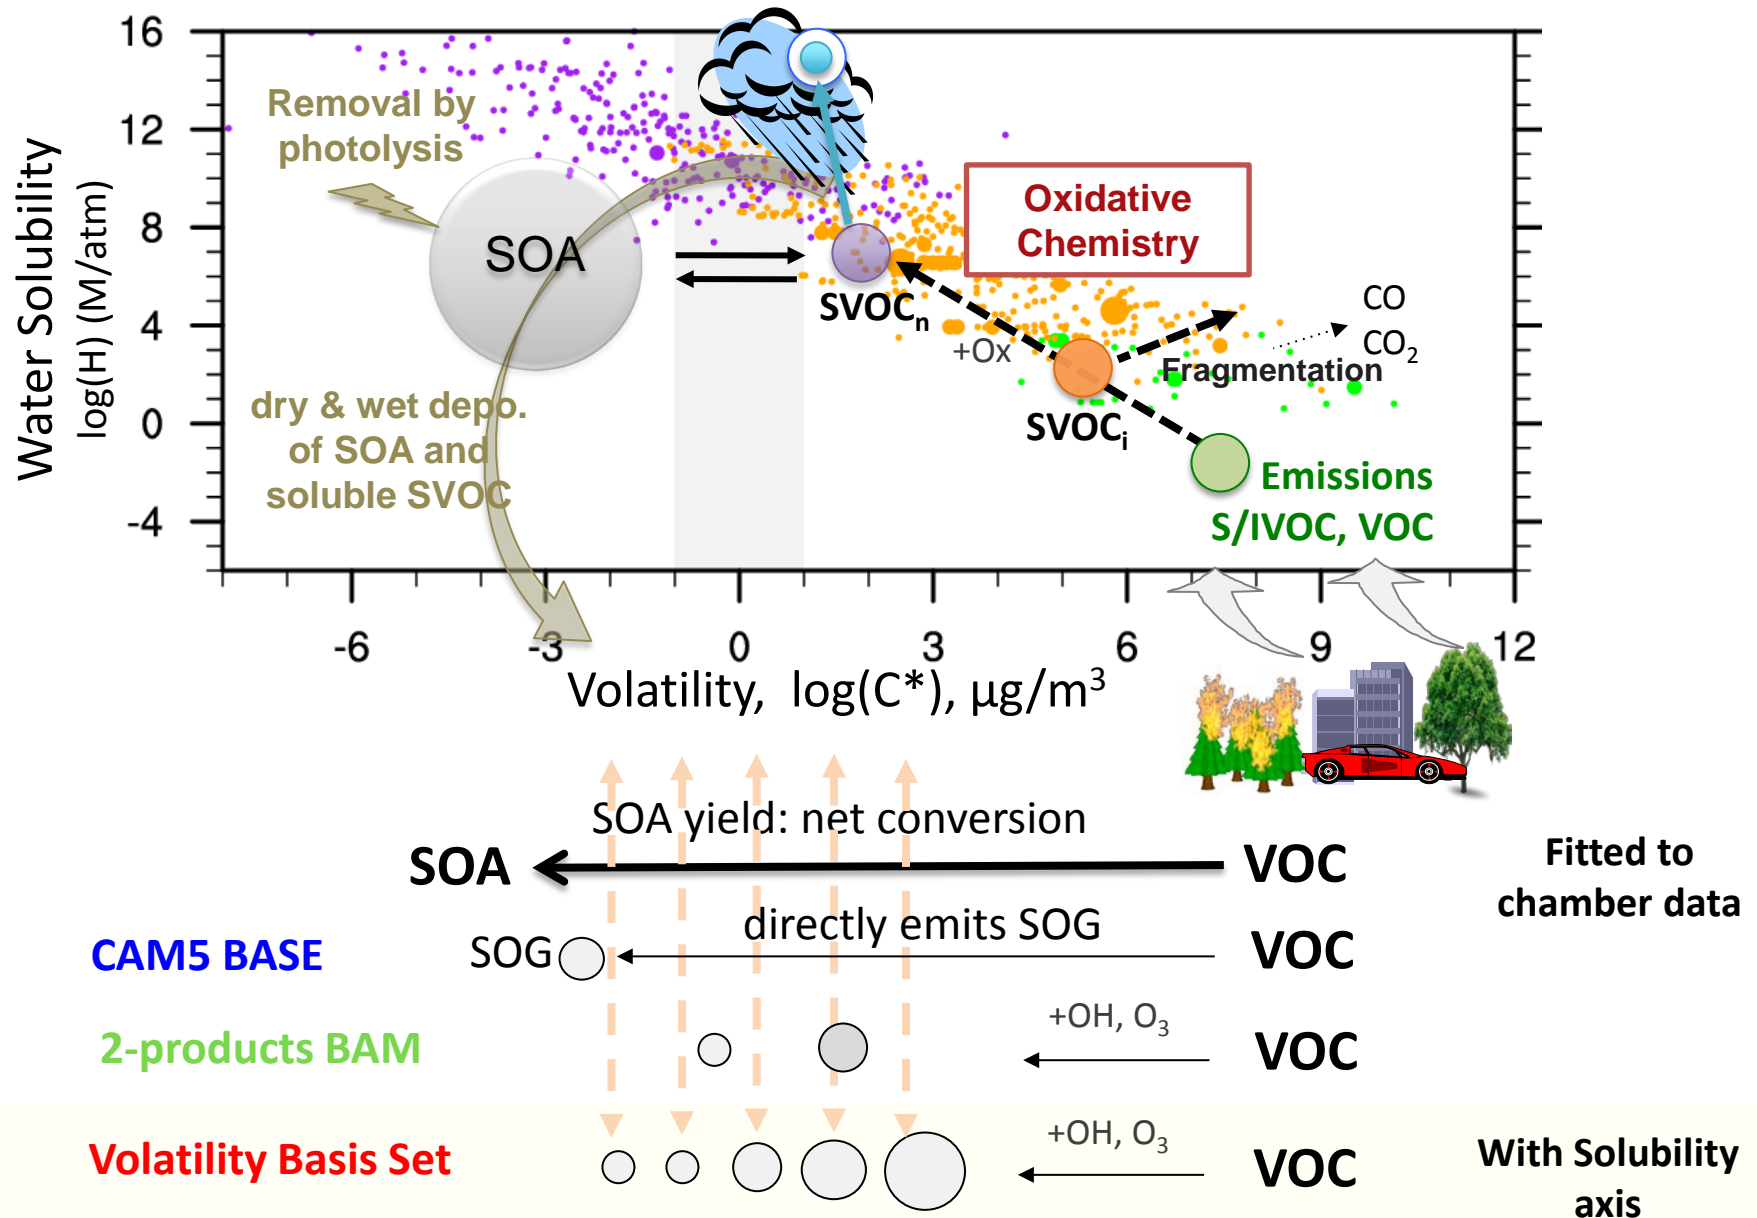

- *Describe the new SOA treatment in CAM5*
- *Discuss the way forward for climate research and for new CMIP runs*

Motivation: Global SOA source is highly uncertain

- Studies constrained by observations point to a source of ~150 Tg/yr
- Current parameterizations mostly fail in predicting those values
- Revised production and removals

Simplistic ways of treating the complex SOA lifecycle

Shortcomings of the *CAM5 BASE* SOA (Liu et al. 2012)

On the production side:

- Does not use oxidants to produce SOG => inaccurate diurnal cycle of SOA, Nb.
- Does not reflect updates in SOA production yields: wall corrected yields indicate a much stronger production

CAM5 BASE: Empirical SOA Yields,
sometimes increased by 50%

2PROD BAM: Historic SOA mass Yields
with wall losses (Heald et al. 2008)

CAM5 VBS: Wall corrected SOA Yields
(Zhang et al. 2014)

- Does not account for S/IVOCs emissions ($\text{C}_{>9}$) which are missing in inventories
- SOA production in the aqueous phase is not included

Shortcomings of the *CAM5 BASE* SOA (Liu et al. 2012)

Evidence for extra removal besides dry and wet deposition of SOA:

- SOA particles can undergo *heterogeneous reactions* with OH, O₃
- SOA particles are sensitive to *UV light* during atmospheric aging:
 - 50% decrease of the condensed phase α -pinene ozonolysis SOA in 1 week of aging (Epstein et al. 2014)
 - Lifetime of \sim 10h of lab. α -pinene ozonolysis SOA under UV lamps (Henry and Donahue, 2012; Wong et al. 2014)
 - Heald et al. 2012: when SOA production is increased to match PBL concentrations, SOA levels in the upper troposphere are largely overpredicted
- Effective SOA photolysis rate (Hodzic et al. 2015, ACP)
 - Ambient aerosols with MAC=0.1 m²/g and QY=1% (1Carbon) JSOA = 0.04% JNO₂
 - 40–60% decrease in SOA yields over 10 days of aging at mid-latitudes in summer

2 new model configurations for SOA production and removal

- **VBS-NY CAM5 run (Hodzic et al. 2015, ACPD):**
updated SOA algorithm uses volatility basis set (VBS)
 - VBS based on the Statistical Oxidation Model fitting of **the wall-corrected SOA yields** (Zhang et al. 2014).
 - Addition of semi-volatile and intermediate volatility precursors (S/IVOC) from anth. and biomass burning sources (Jathar et al. 2014): $E_{SVOC} = 0.6 E_{POA}$ and $E_{IVOC} = 0.2 E_{NMVOC}$
 - S/IVOC yields from explicit chemistry (GECKO-A)
- **VBS CAM5 run:**
 - Volatility dependent Henry's law coeffs
 - **Photolytic SOA loss:** $J_{[SOA]} = 0.04\% J_{[NO_2]}$ (Hodzic et al. 2015, ACP)

30 particle species: 5 volatility bins, 2 modes (Aitken and accumulation) and 3 classes including fossil fuel, biogenic and biomass burning. We also have 15 gas species.

Model configuration

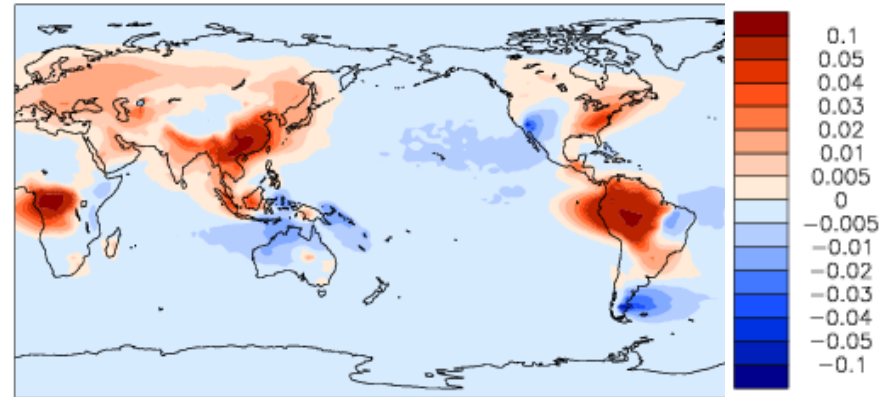

- CAM5.4 (1.9 x 2.5) specified dynamics version, using GEOS5 meteorological analysis (2006-2009).
- MOZART gas-phase chemistry extended to include a better speciation of biogenic and anthropogenic SOA precursors
- SOA precursors emissions:
 - Biogenic MEGAN (Isop, apin, bpin, limon, myrc, sesq)
 - Anthropogenic RCP8.5 (benzene, toluene, xylene and alkanes)
 - Fire from FINN (benzene, toluene, xylene and alkanes)
 - Additional semi-volatile and intermediate volatility organics (S/IVOC) from anthropogenic and biomass burning emissions
- SOA species interact with clouds and the optical calculations

Results: Annual average SOA column burden

BASE SOA burden=0.66 Tg

AOD 550nm: VBS - BASE

VBS SOA burden=0.78 Tg

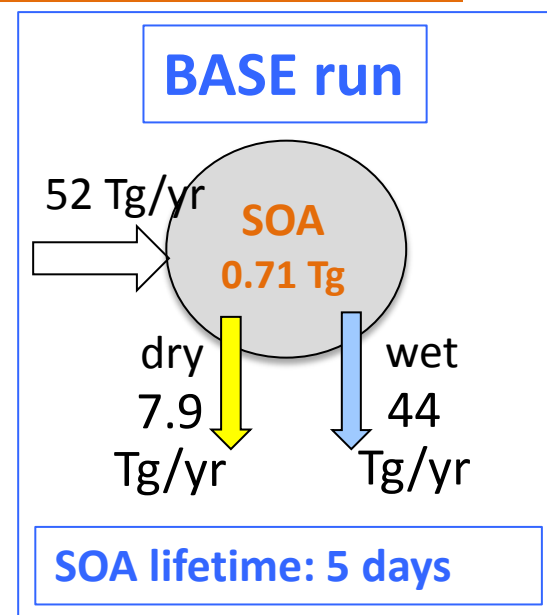

Difference: VBS - BASE

VBS vs. BASE:

- Increased SOA burden in source regions (China, SE U.S., Europe, fire regions)
- Decreased SOA burden in the outflow regions

Results: Annual SOA budgets

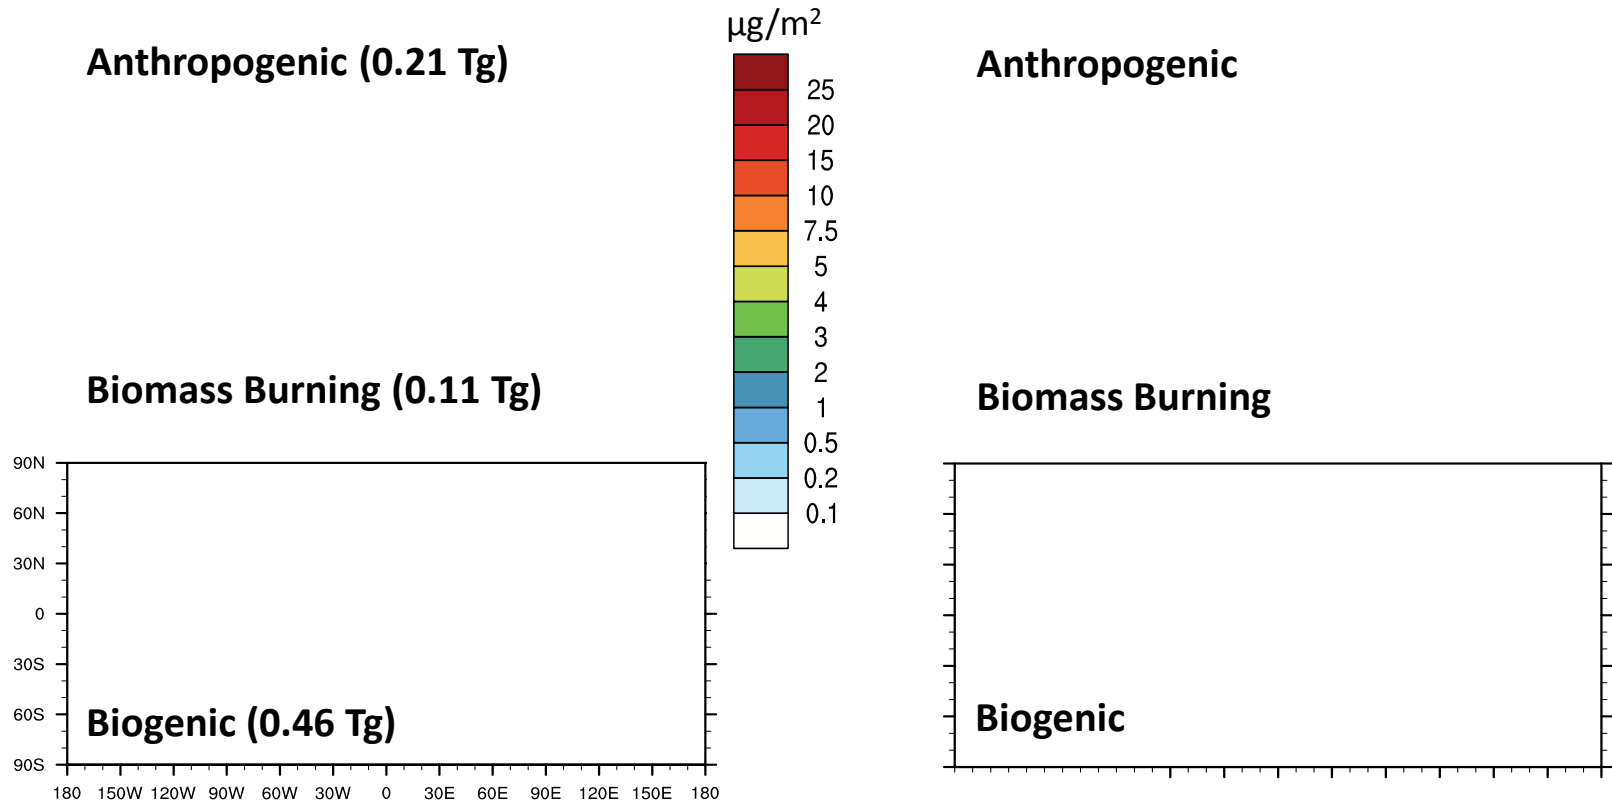

VBS vs. BASE:

- Higher production and higher removals – a more dynamic SOA system
- Updates in the yields alone leads to very high burden

VBS run: source contribution to SOA

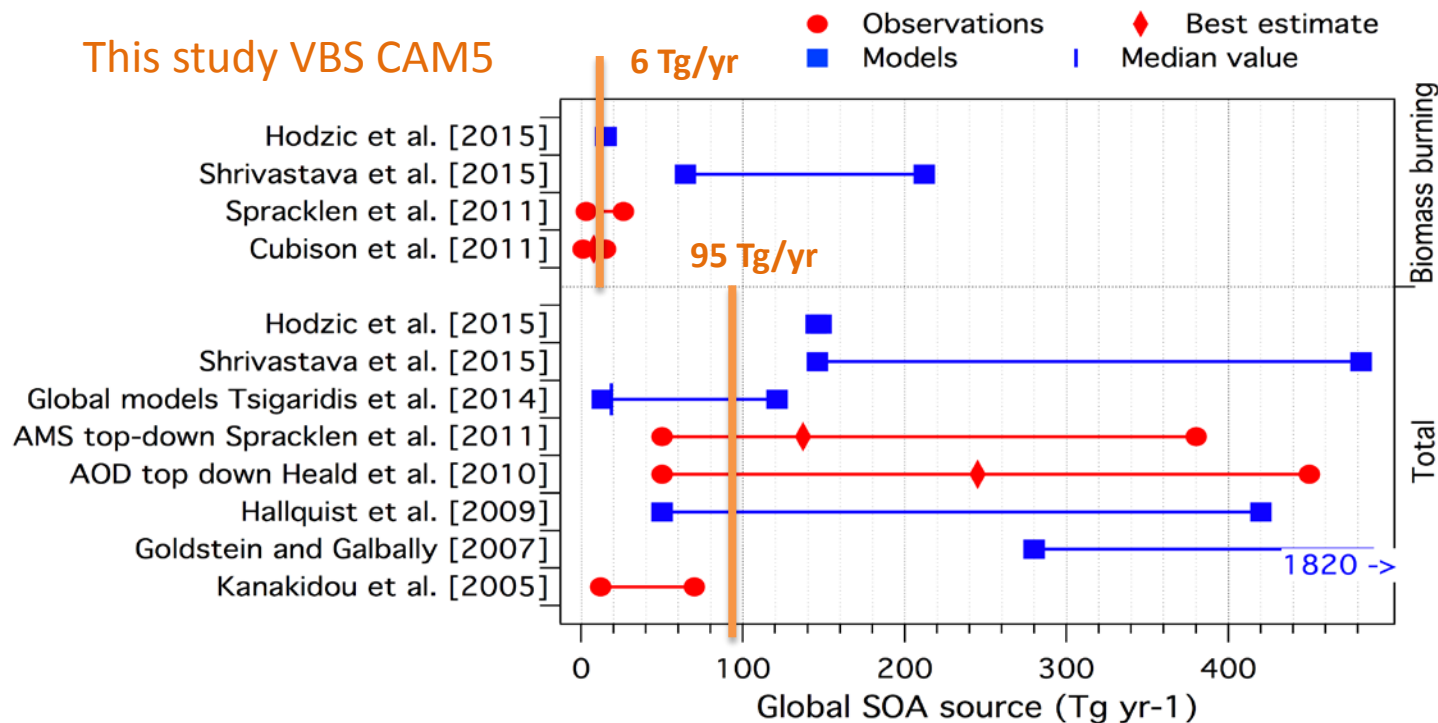

% contribution

- Biogenic emissions are the largest source of SOA globally (although treatment of isoprene is work in progress)
- Anthropogenic sources dominate over China and India

Results: Comparison to previous studies

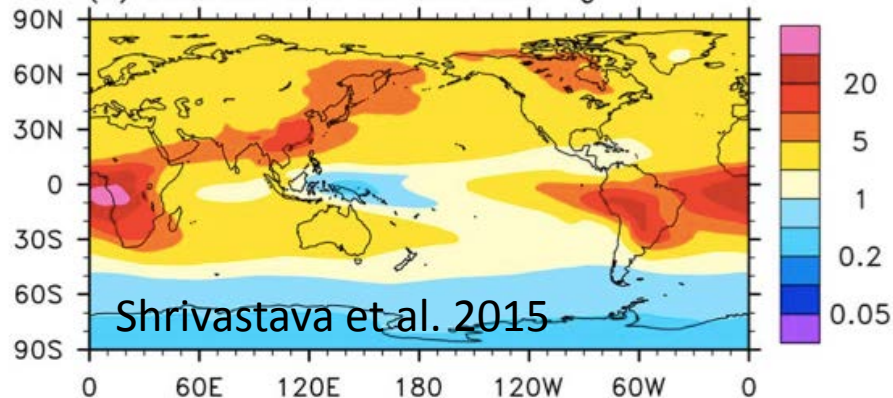

This study VBS CAM5

- Large difference in biomass burning

(a) Biomass SOA burden: 0.11 Tg

(b) Biomass SOA burden: 2.25 Tg

This study VBS CAM5

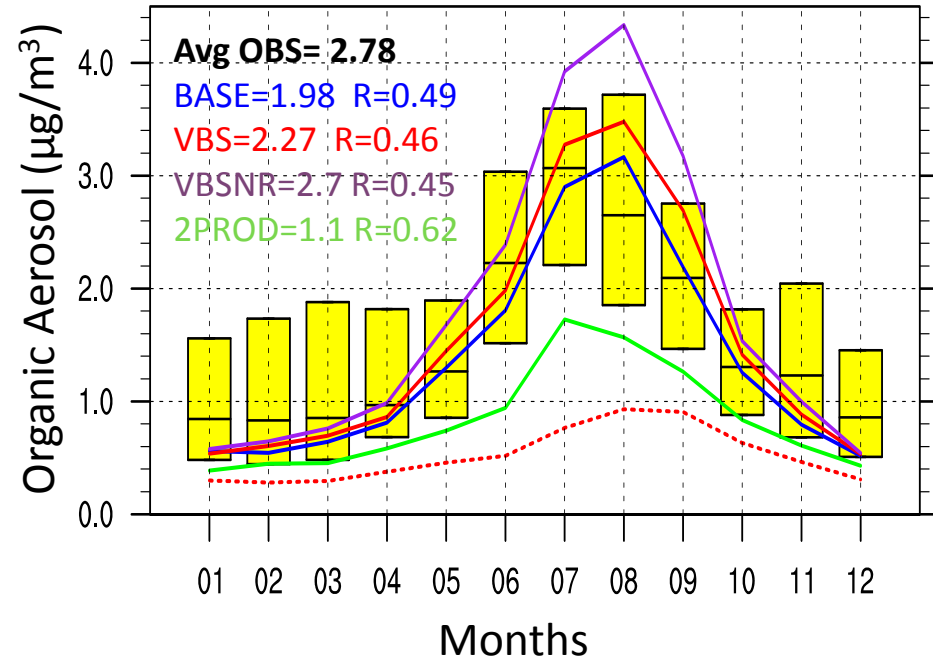

Results: SOA near the surface

- Annual SOA burden (up to 1.5km)

$\mu\text{g}/\text{m}^2$

- Comparison with the U.S. IMPROVE data (2005-2008)

Results: Zonal average SOA ($\mu\text{g}/\text{kg}$)

BASE

VBS_NY: updated
production only

VBS

$\mu\text{g}/\text{kg}$

2PROD - BASE

VBS NY - BASE

VBS - BASE

$\mu\text{g}/\text{kg}$

Results: Zonal average Number Concentrations ($\#/cm^3$)

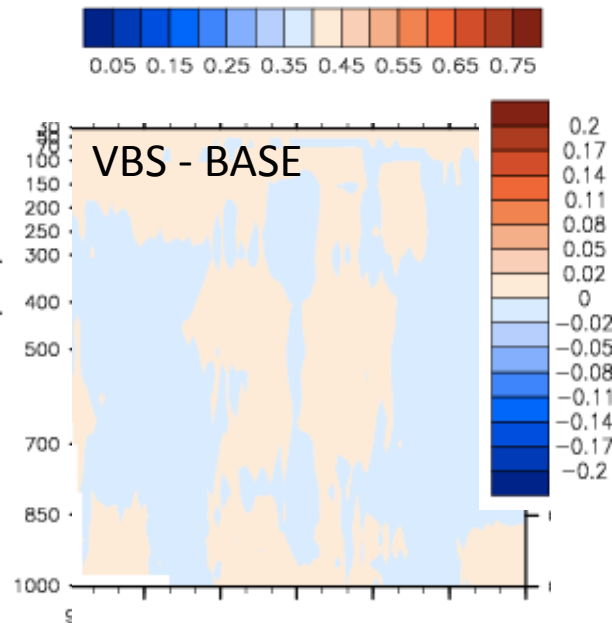

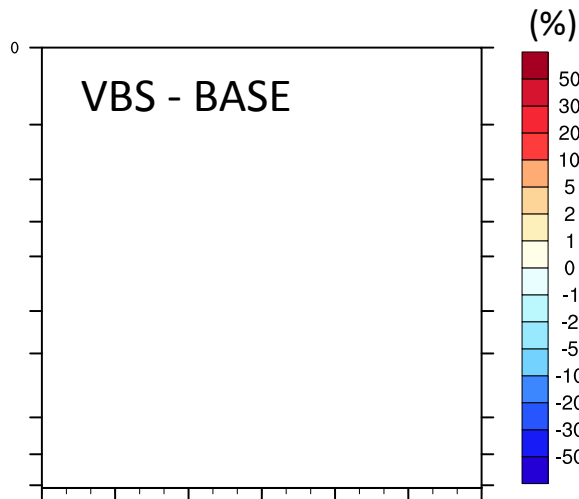

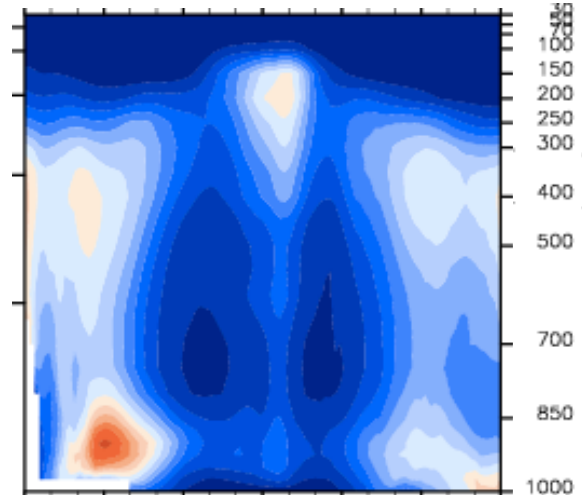

VBS: Accumulation

$\#/cm^3$

VBS: Aitken Number

$\#/cm^3$

VBS: Cloud fraction

Not sure this is meaningful bc we are using specified dynamics

CAM5 VBS 1x1 : Comparisons with SEAC4RS SOA measurements

Ongoing work: Model evaluation at high resolution with campaign data

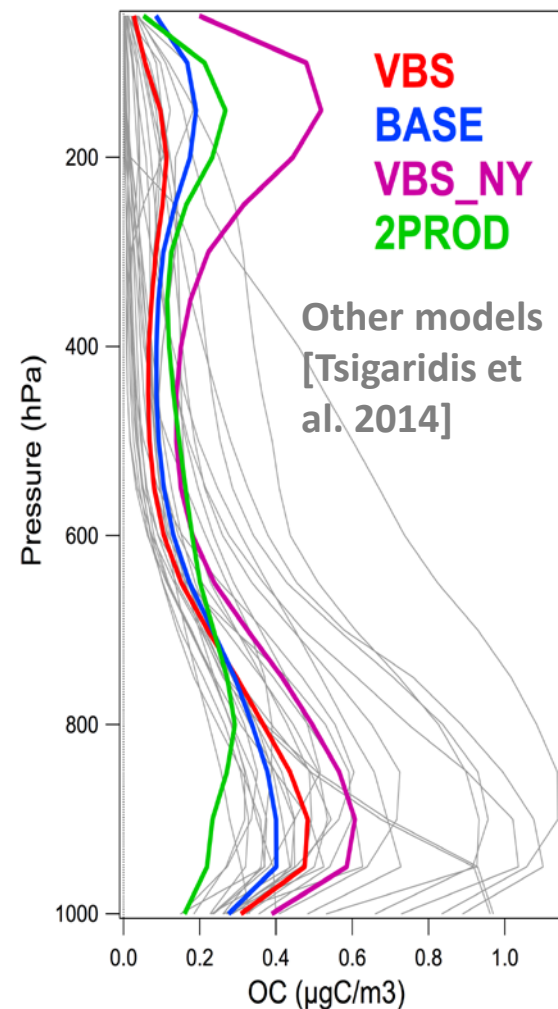

Summary and future work

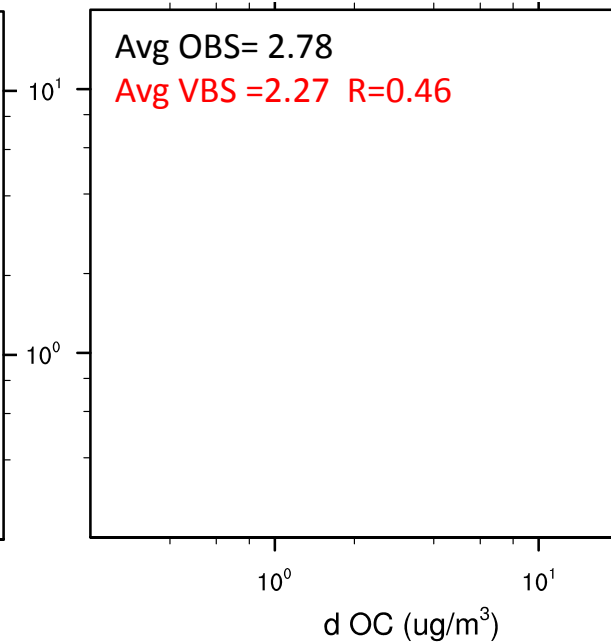

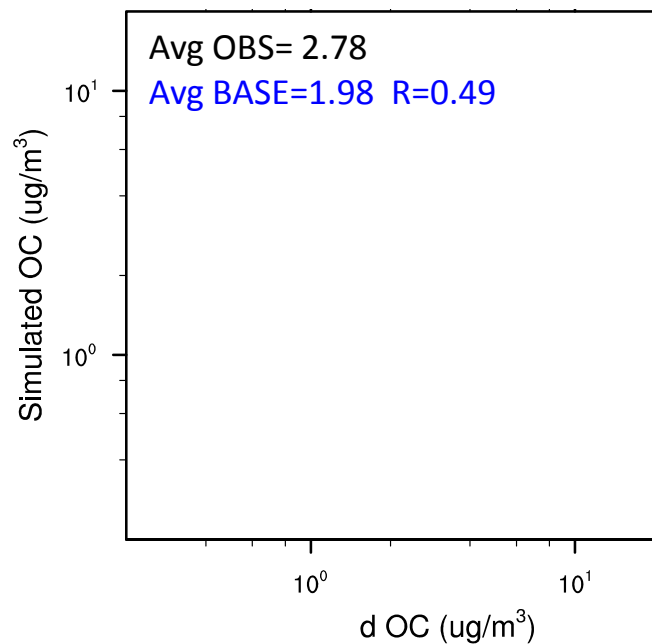

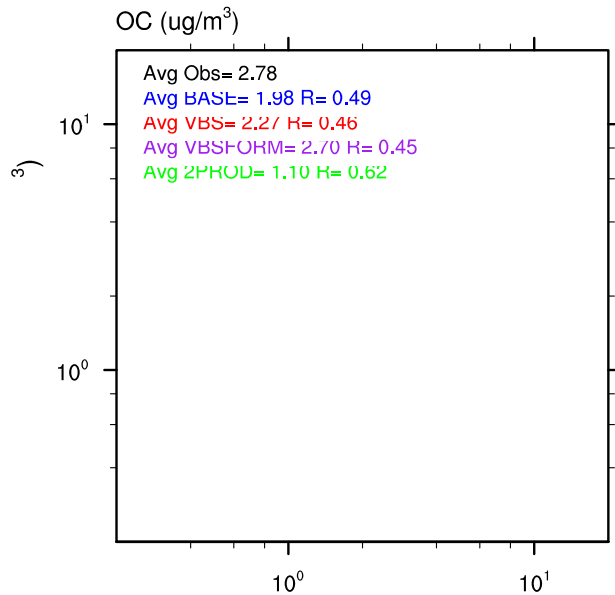

Added a flexible VBS framework into CAM5 that includes updated yields and photolysis removal rates based on recent lab. data, and explicit chemistry

The new SOA approach leads to

- a more dynamic system (higher production, and higher removals),
 - larger concentrations in the near source regions, and lower concentrations in the upper troposphere,
 - Dominance of biogenic sources over BB
 - Improved agreement with profile data
- Examine vertical gradients in OA with upcoming ATOM
 - Revise Isoprene chemistry, and cloud chemistry
 - Work on reducing the number of species for climate runs to 10 SOA, and 5 gas species.

Model evaluation with the U.S. IMPROVE data (2005-2008)

Results: Annual average SOA column burden

BASE SOA burden=0.66 Tg

VBS_NY SOA burden=1.78 Tg

VBS SOA burden=0.78 Tg

2PROD SOA burden=0.93 Tg

VBS vs. BASE:

- Increased SOA burden in source regions (China, SE U.S., Europe, fire regions)
- Decreased SOA burden in the outflow regions

Results: Annual average SOA column burden

Changes due to updated SOA production
