CESM / CISM

Recent CLM developments

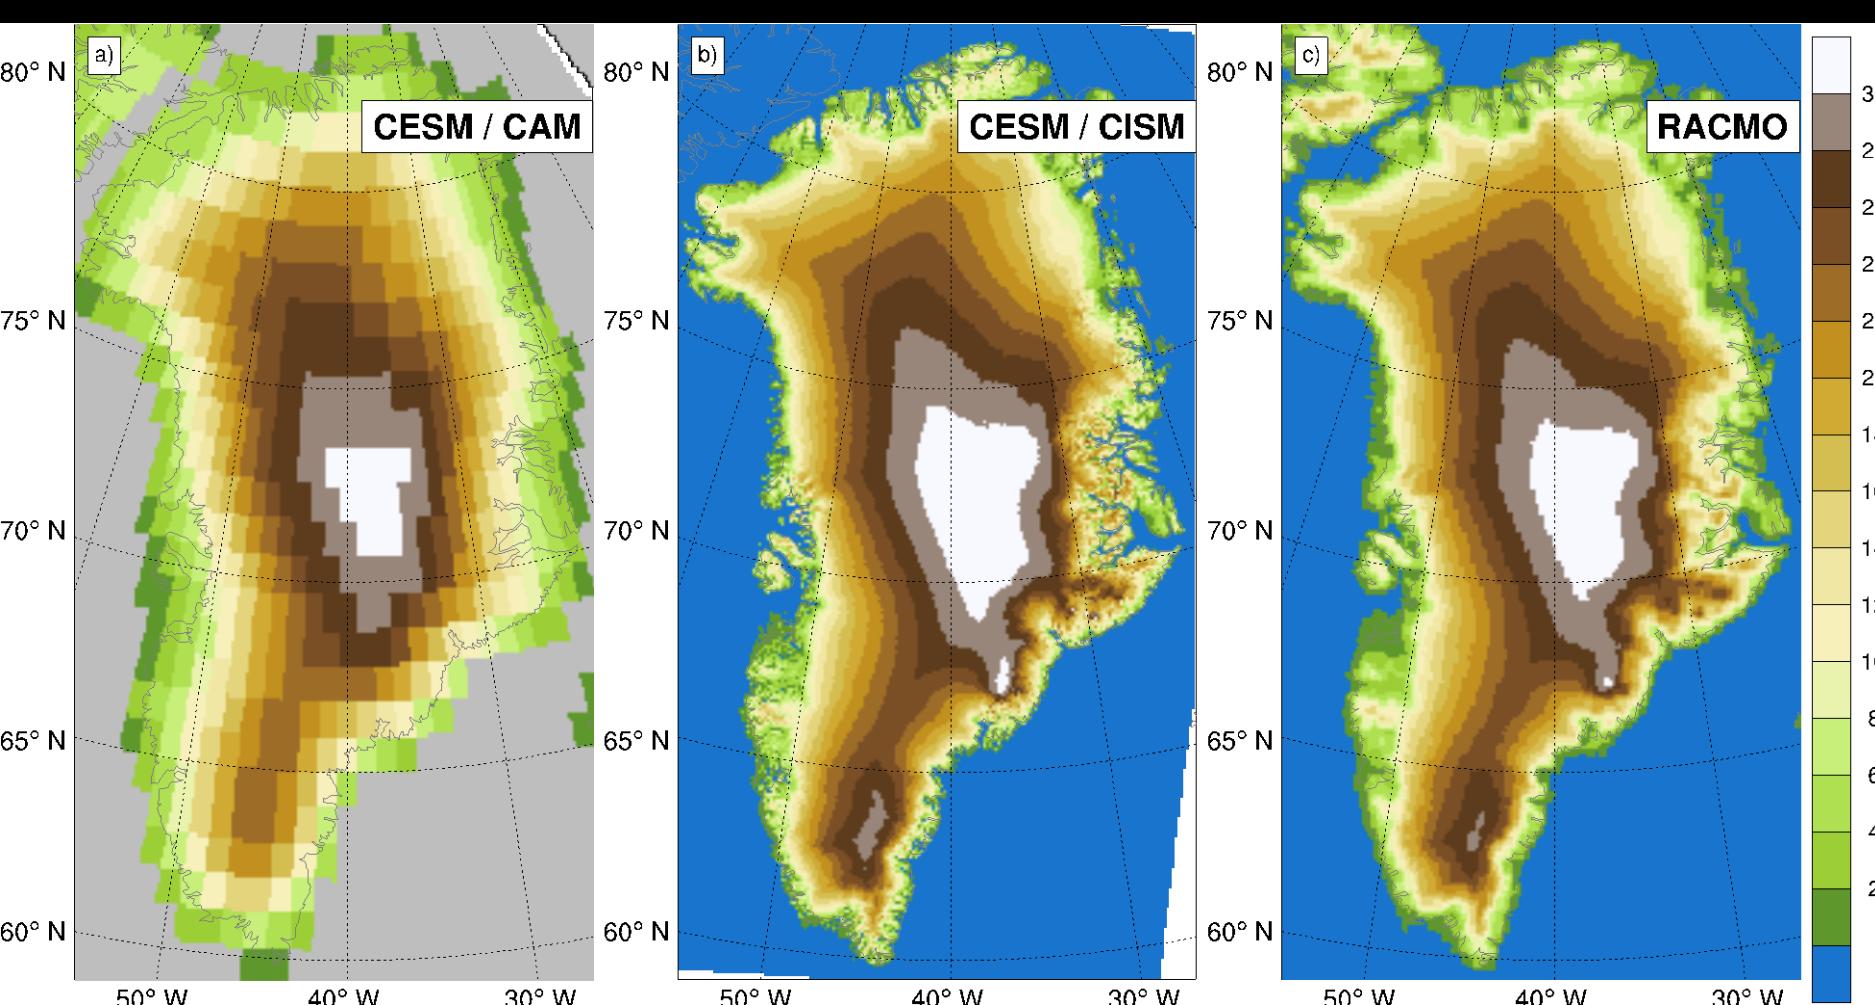

- snow grain size
 - now function of temperature, ranging 54 - 204 microns
- SCF parameter NMELT back to 10
- reset initial snow height for glaciers

Surface winds

m/s

Outstanding issues

- rain bias
- bare ice sublimation still missing in SMB flux
- tundra snow pack problem

221 4xCO₂
years 1-45

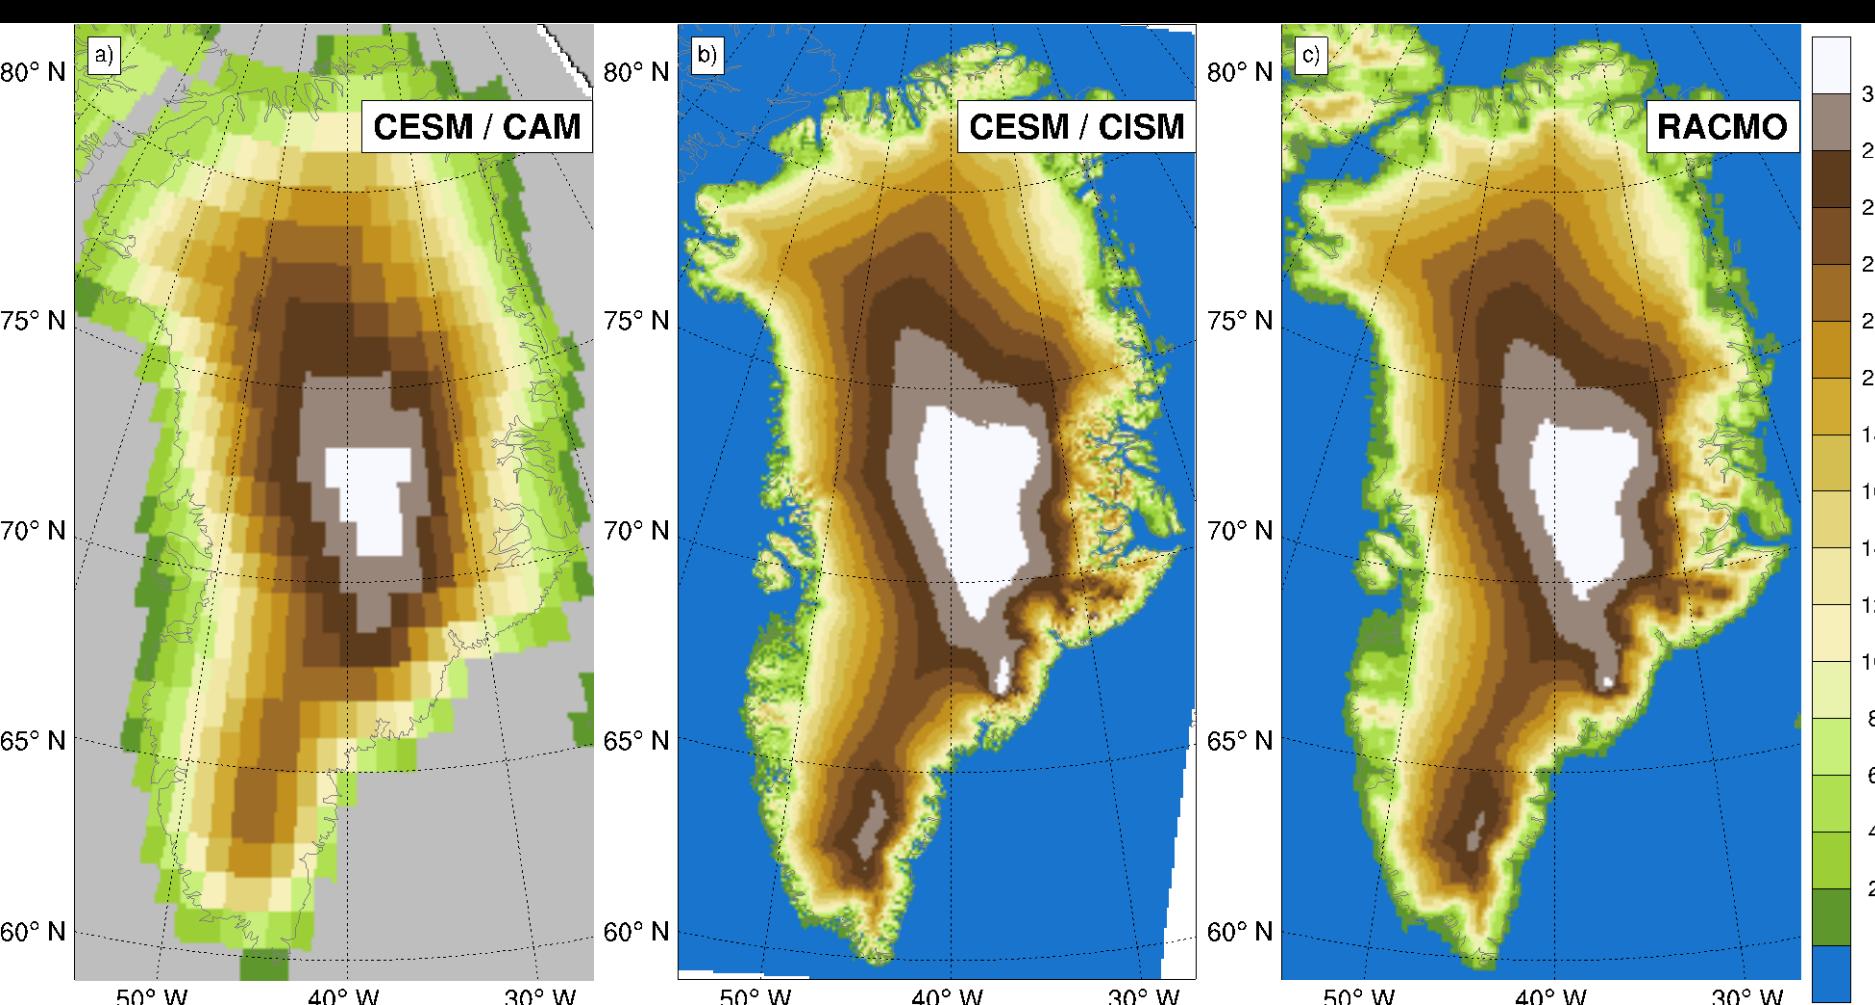

Summary

- CESM2 has a realistic Greenland SMB
- regionally, some compensating energy fluxes
 - e.g. South dome: excessive liquid cloud cover
 - how much is resolution related?
- rain bias
- ice sheet wants to advance into northern tundra
- ready for 1-way coupling
- manuscript on SMB & timeseries

Thanks
