Plant Hydraulic Stress

fundamentally has two jobs:

- how much water stress (β)?
- where in the soil column is the transpiration coming from?

Soil-plant-atmosphere continuum model

Stomatal trade-off

- Need to open pores to obtain CO₂
- But will lose water, which is often a limiting resource
- Plants can open and close stomatal pores in response to environmental conditions
- Different plants have developed different strategies

Carbon dioxide enters, while water and oxygen exit, through a leaf's stomata.

What do we expect going forward?

11 Earth System Models**

**Forced by RCP8.5
emissions through 2100**

How do models perform?

Geophysical Research Letters

RESEARCH LETTER

10.1029/2018GL078131

Key Points:

- Most global vegetation models represent plant water limitation with a rarely tested empirical function based solely on soil moisture
- Carbon cycle uncertainty associated with such soil moisture stress functions is comparable to current

Soil Moisture Stress as a Major Driver of Carbon Cycle Uncertainty

A. T. Trugman¹ , D. Medvigy² , J. S. Mankin^{3,4} , and W. R. L. Anderegg¹

“40-80% of the intermodel variability [in the carbon cycle] due to the functional form of soil moisture limitation”

an increase in drought globally with climate change. We tested the impact of soil moisture stress on plant photosynthetic response to soil moisture stress. We found that soil moisture stress may introduce significant uncertainty in the carbon cycle. We tested the use of the soil moisture limitation function in ecosystem models. We found that soil moisture-limited models capture a certain component of the simulated carbon cycle. Soil moisture limitation accounts for approximately 40–80% of the intermodel variability in the carbon cycle. Our results highlight the importance of soil moisture stress in ecosystem models and illuminate several avenues for improvement.

How do models perform?

Confronting model predictions of carbon fluxes with measurements of Amazon forests subjected to experimental drought

Vegetation Water Use (in a nutshell)

1. Water flows down pressure gradients
2. Plants extract water from the soil by allowing the pressure in their vasculature to fall lower than it is in the soils.
3. But if the pressure gets too low, it can damage the vasculature

Some terminology

1. Water potential \approx pressure
2. Units = Megapascals (MPa)
1 atm \approx 0.1 MPa
3. Symbol: ψ
4. Values are negative

Soil-plant-atmosphere continuum

fundamentally has two jobs:

- how much water stress (β)?
- where is the transpiration coming from?

$\beta \sim [0,1]$
→ Photosynthesis
→ Transpiration

T_a

q_a

Soil Moisture Stress

CLM4.5

- 2 parameters
- empirically derived
- calculates root water uptake from soil potentials
- calculates water stress from soil potentials

$\beta \sim [0,1]$
→ Photosynthesis
→ Transpiration

T_a

q_a

Soil Moisture Stress

CLM4.5

- 2 parameters
- empirically derived

$\beta \sim [0,1]$
→ Photosynthesis
→ Transpiration

1. Conflicts with current theory of vegetation water use
2. Extreme scarcity of soil water potential measurements

T_a

q_a

Plant Hydraulic Stress

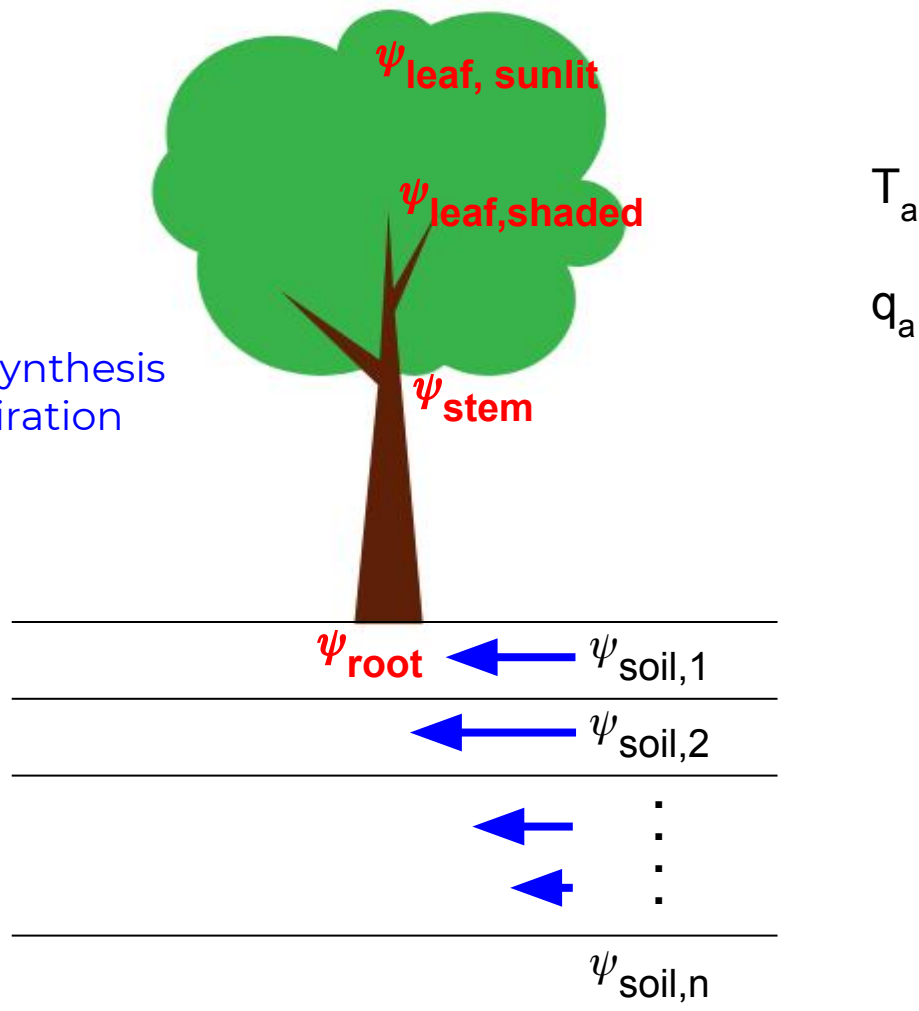

CLM5

- 4 parameters
- adds prognostic plant water potentials
- stronger physical basis
- calculates root water uptake from root water potential
- calculates water stress from leaf water potentials

$\beta \sim [0,1]$

→ Photosynthesis

→ Transpiration

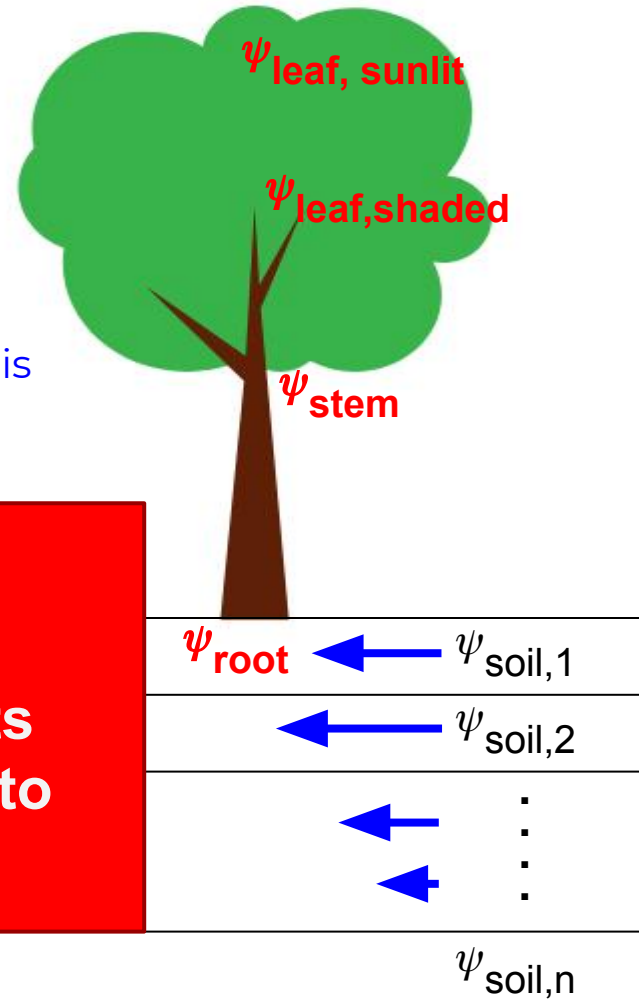

Plant Hydraulic Stress

CLM5

- 4 parameters
- adds prognostic plant

$\beta \sim [0,1]$
→ Photosynthesis
→ Transpiration

1. Better comports with hydraulic theory
2. Water stress variable exists above ground → possible to validate

q_a

Plant Hydraulic Stress

fundamentally has two jobs:

- how much water stress (β)?
- where in the soil column is the transpiration coming from?

Experiment Description

Caxiuanã, Brazil

- Critical biome
- Well-instrumented
- Highly studied
- Drought signal
 - Seasonally dry (Aug-Nov)
 - Experimental precip exclusion plot

Experiment Description

Results

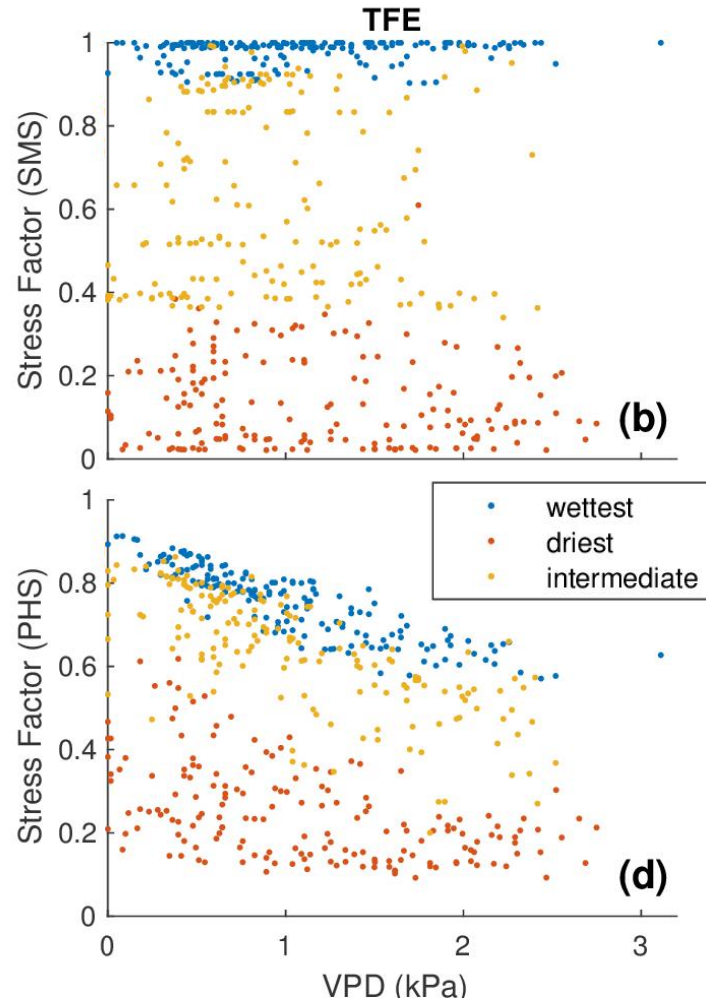

Is PHS
functioning
as
expected?

Soil Moisture Stress

- driven only by soil moisture

Plant Hydraulic Stress

- responds to both:
 - soil moisture
 - VPD

Stress vs.
VPD
(and soil moisture)

Subset for downwelling
solar radiation between
400 and 425 W/m²
(~55th percentile)

Data subdivided by
root-zone soil moisture

Results

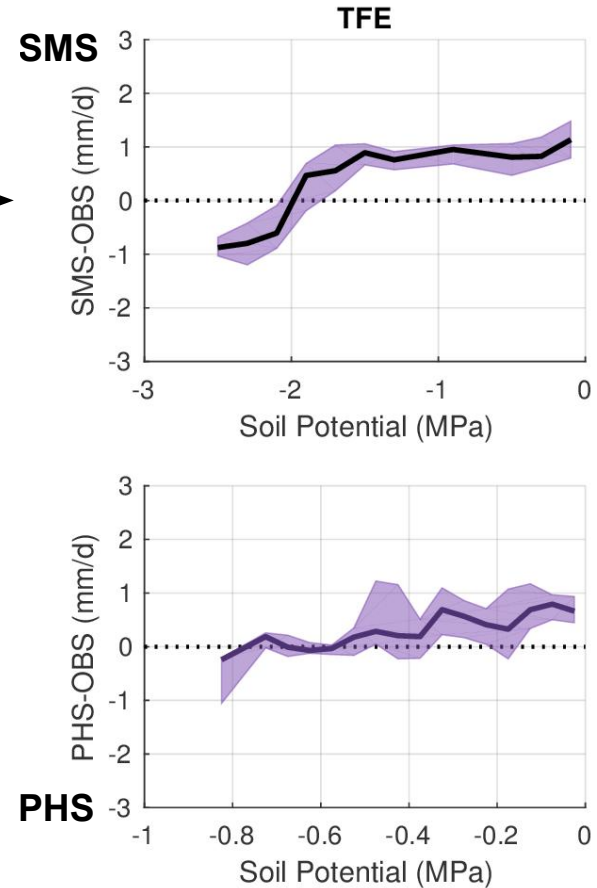

How do we
compare
with field
observations
?

Transpiration: comparison with observations

- Plotting error vs. soil water potential
- Line represents median
- Shading spans interquartile range

- PHS improvements derive from relationship between transpiration and soil potential

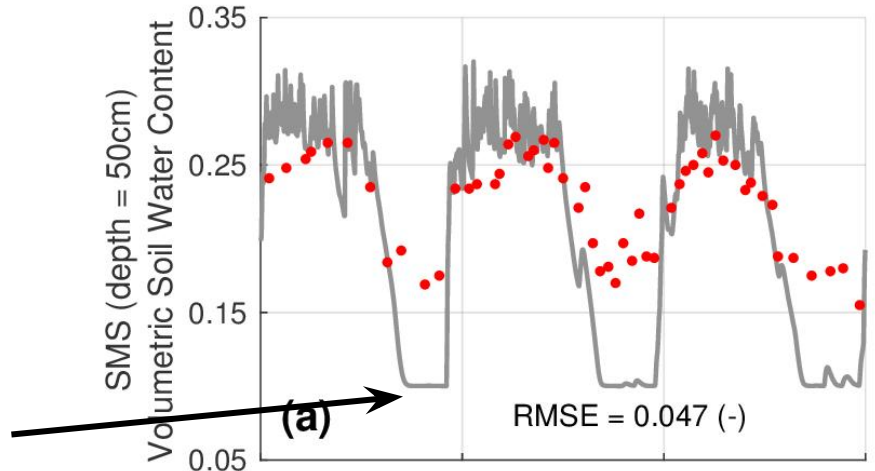

want to be
close to zero

PHS yields improved soil moisture dynamics

SMS root zone is too dry during dry episodes

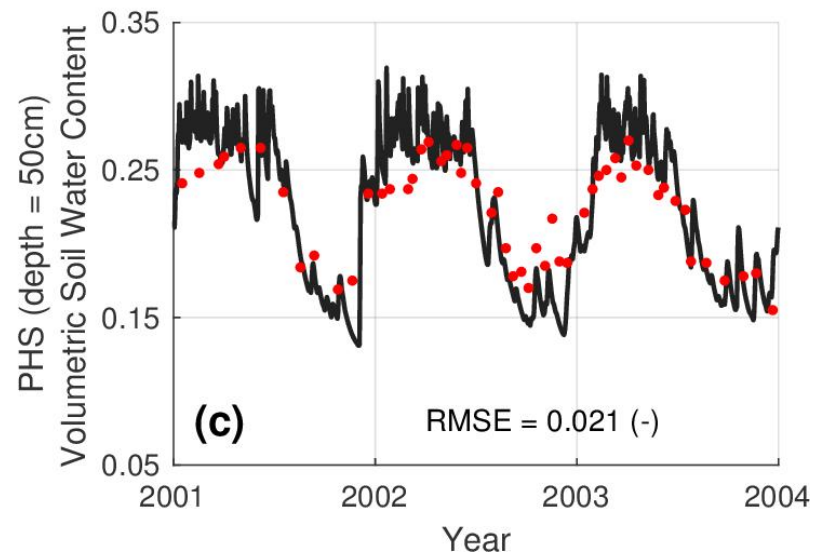

SMS

AMB

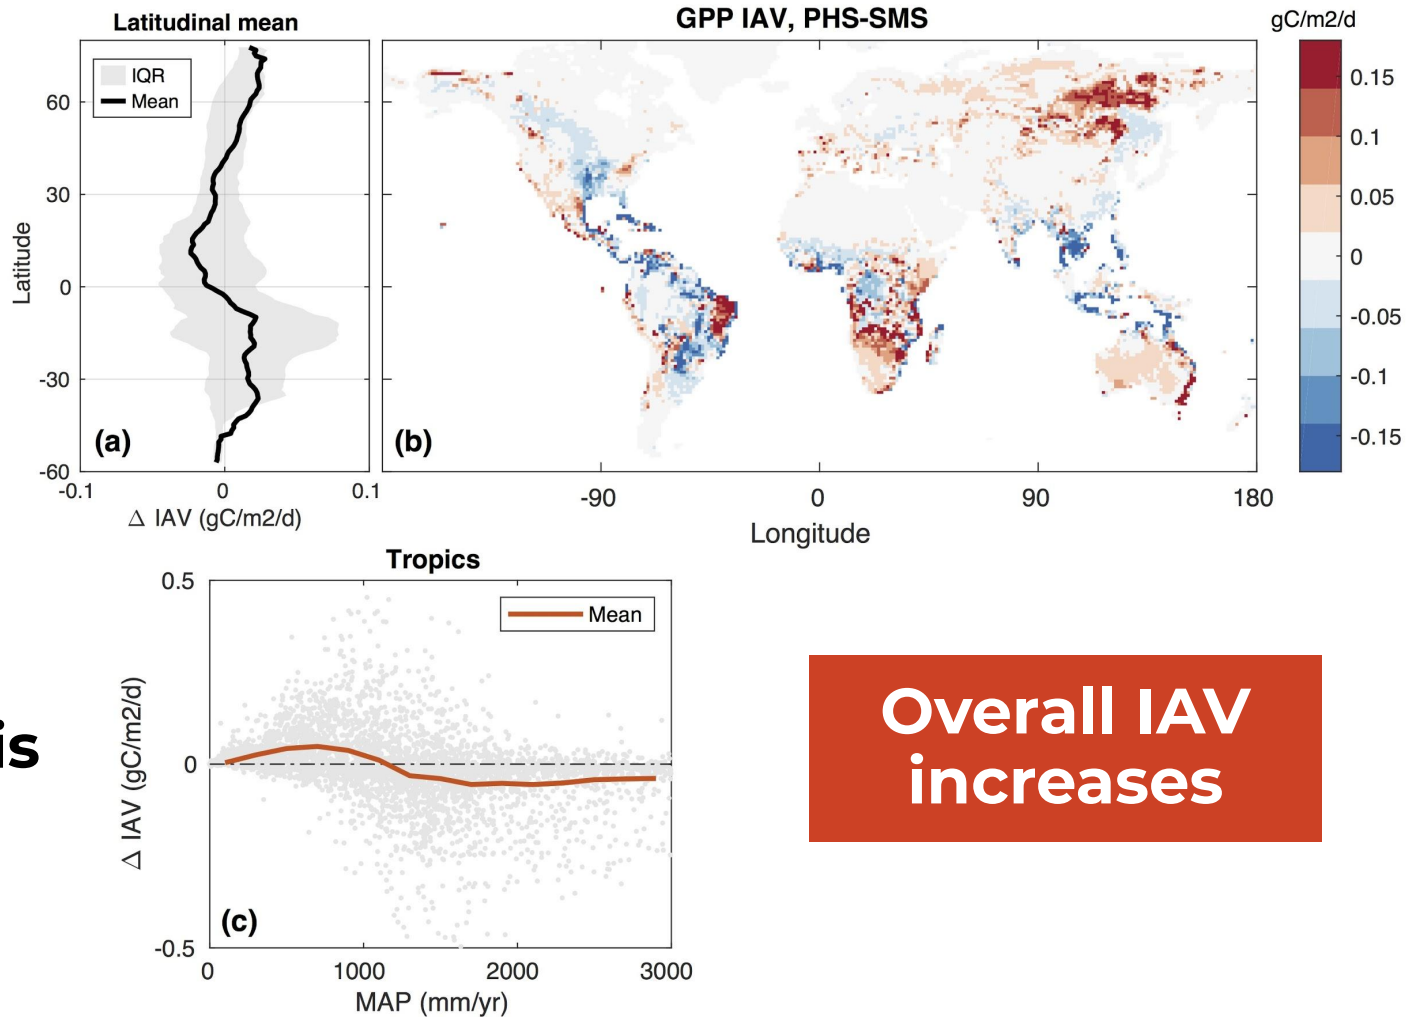

PHS

Global Results

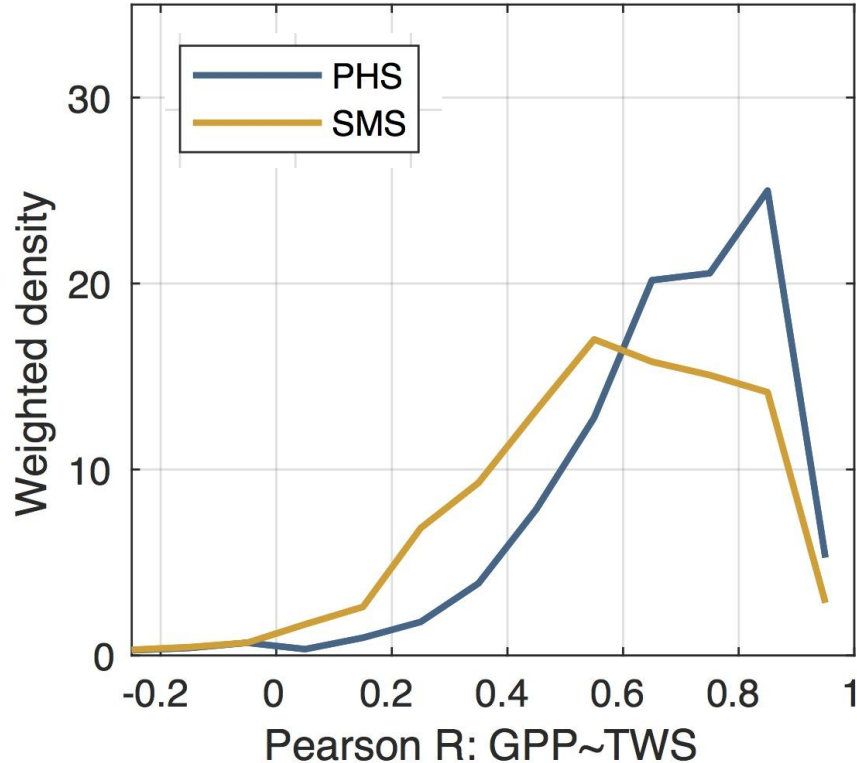

Kennedy et al., *in prep*

How does PHS affect variability in Photosynthesis (GPP)?

Overall IAV increases

GPP correlation with TWS

PHS shows stronger interannual correlations between GPP and terrestrial water storage (TWS)

- histograms represent the distribution of correlations across gridcells in a semi-arid domain
- see Humphrey et al. 2018, which suggests that ESMS significantly underestimate the GPP~TWS relationship

Conclusions:

- PHS is the default vegetation water use parameterization in CLM5/CESM2
- Better comports with hydraulic theory
- Exposes the model to a new suite of observations for validation and parameter estimation
- Creates an entry point for plant hydraulic researchers to test hypotheses on broader spatial scales
